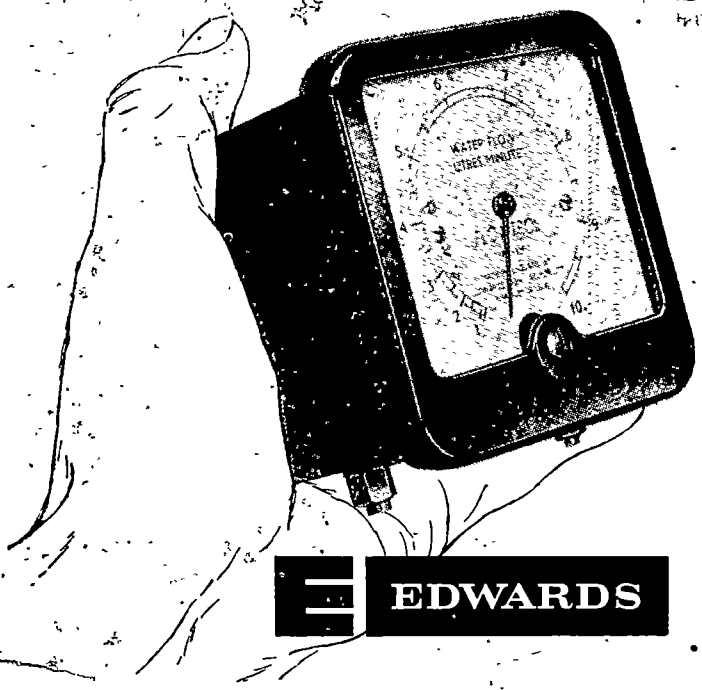
0·5" W.G. to 10,000 p.s.i. –80°C to 1,000°C
(anywhere within those limits – we're in control)

Control and safety systems in aircraft, aircraft engines and space vehicles, have to cope with those kind of extremes of temperature and pressure.

That's why you'll find so many of our pressure and temperature operated switches and valve mechanisms in use in the aerospace industry.

Because they need the kind of accuracy and reliability that is Negretti & Zambra's speciality.

...ough long years of experience. (As early as 1862, Glaisher, the famous balloonist and upper air explorer, was warm in his praises of an aneroid altimeter we made for him.)



And it's a speciality that we apply to our efforts in every field of instrumentation.

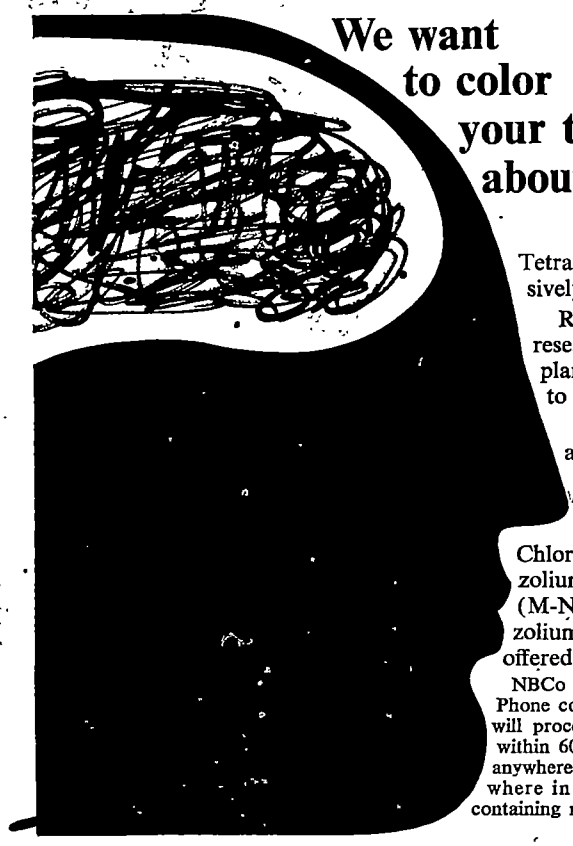
NEGRETTI & ZAMBRA

The name that means precision

NEGRETTI & ZAMBRA LTD., GROUP OFFICES: STOCKLAKE, AYLESBURY, BUCKS. TELEPHONE: AYLESBURY 5931

Set a 'F ne...

for protection against coolant failure



(plus flow measurement if you want it).

An Edwards "Flowtrol" switch Model FS1, or the combined switch and indicator Model FSM1, provides positive protection to water-cooled and liquid-flow equipments against damage resulting from inadequate or excessive flow. Each model operates by pressure differential across an adjustable orifice and can be preset to operate when the required flow-rate limit is reached.

The Model FS1 switch can be adjusted, by modification of the orifice, to suit a specific flow-rate. The Model FSM1 is available in two standard ranges, 0-5 litres/min and 0-10 litres/min. Higher flow-rates can be controlled and measured by mounting the "Flowtrol" in a by-pass to the main flow-line.

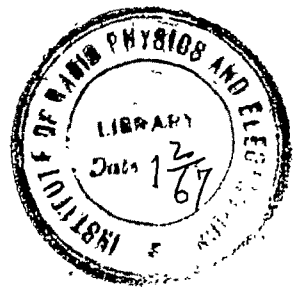
We want to color your thinking about tissue study

Tetrazolium Salts were first described in 1892 but not studied extensively until 1941.

Recent study, however, has confirmed their great value for research investigations in enzymology, histochemistry, bacteriology, plant biology and radiation effects due to their ability to be reduced to an easily identifiable color in viable tissue.



Now, your lab can acquire a complete initial stock of all available Tetrazolium Salts in 100 mg. containers for just $53.50. When ordering, specify NBCo Tetrazolium 32 Kit. Included among the 32 Tetrazolium Salts in the kit are: Triphenyl Tetrazolium Chloride ■ Blue Tetrazolium ■ Iode Nitro Tetrazolium Chloride ■ Neotetrazolium Chloride ■ Tetranitro Blue Tetrazolium Chloride ■ Nitro BT ■ M-Nitro Neotetrazolium Chloride (M-Nitra NT) ■ 3 (4,5 Dimethyl Thiazolyl 1–2) 2,5 Diphenyl Tetrazolium Bromide. Additional salts, derivatives of the preceding, now offered for the first time.

NBCo offers stat service on Tetrazolium Salts. Phone collect, 216-662-0212 (USA only). NBCo will process your order and guarantee shipment within 60 minutes of your call; one-day delivery anywhere in the continental USA, 80 hours anywhere in the world. Send for our free catalog containing more than 3000 items.

INDEX

ABBOTT, Dr. D. C., Harrison, R. B., Tatton, J O'G., and Thomson, Dr. J.: Organochlorine Pesticides in the Atmosphere, 259–61
Abbott, Dr. Walter, and Dawson, C. E: Responses of some Anomuran and Brachyuran Crustaceans to High Speed Centrifugation, 1320
Abbrecht, Dr. Peter H., Malvin, Dr. R. L., and Vander, A. J.: Renal Production of Erythropoietin and Renin after Experimental Kidney Infarction, 1318
Abdel-Latif Dr. Ata A.: Acetylcholine and the Incorporation of [^{32}P] Phosphate into Phospholipids and Phosphoproteins of Nerve Endings of Developing Rat Brain, 530
Aberdeen: Fisheries Research at, 673
University of, Appointment, 5
Aberystwyth: Meeting on Plant Terpenoids at (Dr J. Friend), 1128
(+)-Abscisin II ((+)-Dormin): Identification of the Yellow Lupin Growth Inhibitor as (Dr. J. W. Cornforth et *al.*), 742
Absorption of Ethylene by Self-indicating Soda-lime (R. Nichols and A. Topping), 217
Absorption of High-energy Gamma-rays within Quasars and Other Radio Sources (Dr. J. V. Jelley), 472–5
Abstracts for Physics, 112
Abstracts on Tape, 557
Acarina, from Ground Holes: Recovery of Unengorged Larval Trombiculid Mites (Dr. W D. Kundin et *al.*), 1213
Accelerators: Sites for, 337
Accident Research (W. Haddon, jun., E A. Suchman and D. Klein), *review* by J. C. Scott, 349
Acetal. Reactions of the Hydroxyl Radical in the Radiolysis of Aqueous Solutions of Di-ethyl (Dr. R. A. Basson and P. M. Champion), 1398
Acetone-precipitated Soluble Proteins: Elimination of Non-specific Antibodies from Rabbit Antisera using (B. Schmidt et *al.*), 32
Acetylacetone: Extraction of Organic Matter from Soils by means of Ultrasonic Dispersion in Aqueous (R. L. Halstead et *al.*), 1430
Acetylcholine Conformation: Effects of Solvents on (Dr. J. H. Fellman and T. S. Fujita), 848-50
Acetylcholine, and the Incorporation of [^{32}P] Phosphate into Phospholipids and Phosphoproteins of Nerve Endings of Developing Rat Brain (Dr. A. A. Abdel-Latif), 530
N-Acetylhexosamines and *N*-Acetylneuraminic Acid by Barium Hydroxide Treatment: Chromogen Formation and Degradation of (Dr. S. Ohkuma and Dr. C. Miyauchi), 190
N-Acetyl-D-mannosamine to Mammals: Administration of (S. M. Amir, Dr. S. A. Barker, W. R. Butt, Dr. A. C. Crooke and A. G. Davies), 976
N-Acetylneuraminic Acid by Barium Hydroxide Treatment Chromogen Formation and Degradation of *N*-Acetylhexosamines and (Dr. S. Ohkuma and Dr. C. Miyauchi), 190
Acetylthiouramil Formation of Oxazolo(5,4-*d*)pyrimidines: Transacylation of Acetyluramil or (T. Nishiwaki), 737
Acid Hydrolysis of Pentammine Cobalt Complex Ions. Mechanism of the (S. H. Laurie), 181
Acid Mucopolysaccharide isolated from Human Gastric Juice: Infra-red Spectroscopic Investigations of a New (T. Terho et *al.*), 198
Acid Phosphatase Isoenzymes in Gaucher's Disease, Prostatic Carcinoma and Multiple Myeloma. Electrophoretic Separation of Serum (Dr. A. F. Goldberg et *al.*), 41–3
Acid Sites on Silica-Alumina: Lewis and Bronsted (N. W. Cant and Dr. L. H. Little), 69
Acidic Glycoproteins on the Development of Sea Urchin Eggs: Morphogenetic Effects of (Dr. R. Lallier), 99
Acids: Hydrolysis of Soil Nitrogen by Strong (Dr J G. Quinn and Dr. M. Salomon), 664
Acoustics: Non-linear, Meeting at Birmingham (Dr. B. K. Gazey), 803
Actidione in *Chlorella*, Inhibition of Protein Synthesis by (I. Morris), 1190–2
Actin and Myosin during Clearing: Interaction of (E. Eisenberg and Dr. C. Moos), 529
Actinomycin *D* and Deoxyribonucleic Acid *In vivo* Complex Formation of (Dr. F. F. Becker, A. A. Margolis and Prof. W. Troll), 84
Actinomycin D: Elevation of Alkaline Phosphatase Activity in the Intestine of the Chick Embryo by (Dr. R. D. Grey and Prof. F. Moog), 418
Actinomycin *D* and Puromycin on Chromosomes of Cultured Human Leucocytes: Effects of (R. L. Neu, Dr. J. Carneiro Leão and Prof L. I Gardner), 881
'Activated Ester' *Trismonoalkylaminoboranes* in Organic Synthesis. the Exploitation of a New Type of (T. Levitt and Dr. A. Pelter), 299
Actomyosin-like Protein from Crayfish Nerve: a Possible Molecular Explanation of Permeability Changes during Excitation (Dr. K. Bowler and Dr. C. J. Duncan), 642
Acton, Loren W., et *al.*: Resolution of X-ray Sources at Low Galactic Longitude, 920–3
Adam, Dr. J.: Atomic and Ionic Impact Phenomena on Metal Surfaces, *review*, 347
Adam, William S.: Fine Structure of Experimentally Produced Subsynovial Carbon Granuloma, 771
Adams, Prof. C. W. M.: Meeting on Atherosclerosis at Athens, 351–3
Neurohistochemistry, *review* by Prof. G. J. Cunningham, 686
Adams, Dr. G. E., Michael, B. D., and Land, Dr. E. J.: Pulse Radiolysis Investigations of Unimolecular Elimination Reactions in Free Radicals produced by OH Addition to Hydroxybenzenes, 293
Adamson, Dr. Richard H., et *al* : Antitumour Activity of *N*-Hydroxyurethane, 984
Adaptation Level of the Eye: Critical Flicker Fusion Perimetry and the (Dr. T. Shipley and A. Fry), 1315–7
Adaptation: Neuroendocrine Control of (K. Lissák and E. Endroczi), *review* by Dr. E. T. Bell, 568
Addink, Dr. N. W. H.: Suppression of Halo on Photographic Plates used in Mass Spectrometry, 1168
Adenine-5′-monophosphoric Acid: Porphyria induced in Rats by Orotic Acid and the Effect of (Dr. A. Gajdos et *al*), 974
Adenine, Utilization of, but not Nitrate as Nitrogen Source by *Prototheca zopfii* (J. L. Stacey and Dr. F. J. Casselton), 862
Adenosine Diphosphate and Adrenaline: Secondary Clumping Effect in Human Citrated Platelet-rich Plasma produced by (Dr. D. C. Macmillan), 140–4
Adenosine Diphosphate Binding Sites on Human Platelets: An Estimate of the Number of (Dr. J R. Hampton and Dr. J. R. A. Mitchell), 245
ATPase Activity, Extrusion of, from Pinocytotic Vesicles of Abutting Endothelium and Smooth Muscle to the Internal Elastic Membrane of the Major Arterial Circle of the Iris of Rabbits (Dr. C. A. Santos-Buch), 600–2
Adenosine Triphosphate in Blood: Importance of the Mechanisms of Blood Coagulation in the Breakdown of (J. J. Marr et *al.*), 1306–8
Adenosine Triphosphate in the Skin Venom of Amphibia: Presence of (Prof. M. Vialli and L. Bolognani), 1324
Adenosine Triphosphate Driving the Sodium Pump backwards to form (Dr. P J Garrahan and Dr. I. M. Glynn), 1414
Adenovirus Antibody and Antibody to 'T' Antigen (Neoantigen) Location in Gamma-globulin (Dr. A. C. Hollinshead, Dr. T. C. Alford, Dr. H. C. Turner and Dr. R. J Huebner), 423
Adenovirus Type 3 in Hamsters: Oncogenicity of Bovine (Dr J. H. Darbyshire), 102
Adenovirus Type 12-infected Cells: Isolation and Analysis of Adenovirus 12 Sub-units from (Dr. A. C. Hollinshead and Dr. R. J. Huebner), 890
Adhesion of Atmospheric Dustfall Particles to a Glass Slide (Dr. M. Corn and F Stein), 60
Adjuvant Principle of Pertussis Vaccine in the Mouse (R. E. Pieroni and L. Levine), 1419
Adrenal Cortex. α-Glycerophosphate Dehydrogenase in Mouse (S. Sivaram and D. R. Sharma), 855
Adrenal 17-Hydroxycorticosteroid in the Dog: Anaphylactic Shock and the Secretion of (Prof. T Suzuki et *al.*), 1185
Adrenal Necrosis from 9,10-Dimethyl-1,2-benzanthracene in Rats: Liver Injury and the Prevention of Massive (Dr. D N. Wheatley et *al.*), 387–9
Adrenal Necrosis induced by 7-Hydroxymethyl-12-methylbenz(*a*)anthracene and its Prevention (Dr. D. N. Wheatley, Miss A. G. Hamilton, Prof. A. R. Currie, Prof. E. Boyland and Dr. P. Sims), 1311
Adrenaline: Cholinergic Mechanism of Depressor Response to Small Doses of (Dr. L P. McCarty and Dr. M. B. Chenoweth), 750
Adrenaline Secondary Clumping Effect in Human Citrated Platelet-rich Plasma produced by Adenosine Diphosphate and (Dr. D. C. Macmillan), 140–4
Adrenergic Beta-receptor Blockade and Anaerobic Metabolism (Dr. C. Furberg), 888
Adrenocorticotrophic Hormone: Stretchings and Yawnings induced by (Prof G. L. Gessa et *al.*), 426
Adsorption of Caesium Tetraphenylborate from Aqueous Solutions on Glass, Polyethylene and Polytetrafluoroethylene (I. A. Skul'skii and V. V. Glasmov), 631
Adsorption during Filtration of Aqueous Solutions of Polycyclic Aromatic Hydrocarbons: Losses due to (Dr. M. N. Inscoe), 1083–5
Adsorption Isotherms at Low Concentrations. Gas Chromatographic Determination of Non-linear (Dr. J. F. Parcher and Dr. P. Urone), 628
Adsorption of Lactate Dehydrogenase to the Particulate Fraction of Homogenized Skeletal Muscle (Dr. F. O. Hultin, C. Westort and J H. Southard), 853
Adventitious Organs by *Pharbitis* Embryos: *In vitro* Formation of (Dr. S. Matsubara and Dr. R. Nakahira), 1208–10
Aedes aegypti L. Cells grown *in vitro*: Establishment of a Line of Mosquito (T. D. C. Grace), 366
Aegilops umbellulata Chromosome Segment incorporated in Wheat: Variation associated with an (Dr. C. R. Bhatia and Dr. H. H. Smith), 1425
Aerosols on the Moon and in Outer Space: Alveolar Deposition of (Dr. J. M. Beeckmans), 208
Africa: Forest and Savanna: Tropical Plant Ecology with Special Reference to West (Dr. B Hopkins), *review* by F. N. Hepper, 237
Insects in Southern (Dr. B. Smit), *review* by Sir Vincent Wigglesworth, 1127
Physical Research in, 1324
Agar: Discriminating Power of Rodent DNA on Incubation in (Dr. A. McLaren and Dr. P. M. B. Walker), 486–90
Agar Gel Electrophoresis (Dr. R. J. Wieme), *review* by Dr. R. Consden, 1125
Age of the Aliwal Shoal, South Africa (Dr. A. N. Carter), 507
Age of Alluvial Clays in the Western Gezira, Republic of the Sudan (M. A J Williams), 270
Age of Basal Schists in the British Solomon Islands: Potassium–Argon Measurements of the (Dr. J. R. Richards et *al.*), 1251
Age and Chromosomes (Dr. E. H Kleisner de Galán), 1324
Age: Guinea-pig Mast Cells and (R. St. J. Buxton), 1103
Age of Plutonic Intrusives on Cape Colville Peninsula and Cuvier Island, New Zealand: Potassium–Argon (Dr. J. R. Richards et *al.*), 725
Ageing and the Bauschinger Effect in Mild Steel (Prof. N. L. Svensson), 290
Aggregates in Sea-water Interaction of Bubbles and Bacteria in the Formation of Organic (R. T. Barber), 257
Aggregation in Lymphocytes: Variability of Ribosomal (Dr. H A Johnson et *al.*), 420
Aggregation in the Variable-frequency Thromboviscometer Platelet (M. C Rozenberg and L. Dintenfass), 525–7
Aggregens: Structure Development in (Prof. M. Moskowitz, Dr. G. F. Amborski and C. H. Wieker), 1047–9
Agin, Prof. D., and Holtzman D : Glass Microelectrodes. the Origin and Elimination of Tip Potentials, 1194
Aging: Advances in Biology of Skin, Vol. 6 (edited by W. Montagna), *review* by Prof. P. L Krohn, 121

Aging and the Nervous System: Behavior (edited by A. T. Welford and J. E. Birren), *review* by Prof P L. Krohn, 121
Agricultural Insects of Ghana (compiled by J. Forsyth), *review* by R. F Avery, 463
Agriculture: Atomic, 1222
Agriculture and Climate Unesco Symposium at Reading (L. P. Smith), 1117–9
Aguilar-Santos, Dr Gertrudes, and Doty, Prof. M. S.: Caulerpicin, a Toxic Constituent of *Caulerpa*, 990
Aharoni, J.: Special Theory of Relativity, Second edition, *review* by Dr. S. Zienau, 1017
Air: Determination of Toxic Substances in (edited by N. W. Hanson *et al.*). Revised edition, *review* by A. A. Christie, 913
Air Sacs and Muscle Fibres in the Imago of *Oryctes rhinoceros*: Distribution of Fat Body around the (K. S. S. Nair and G. K. Karnavar), 1207
Aircraft Noise. Parliament in Britain, 558
Al-Adhami, L., and Millen, Prof. D. J.: Band-broadening in Infra-red Spectra of Gaseous Hydrogen-bonded Complexes, 1291
Alakhov, Yu. B., *et al.*: Mass Spectrometric Determination of the Amino-acid Sequence of Peptides, 361–6
Alanosine, a New Antiviral and Antitumour Agent isolated from a *Streptomyces* (Y. K. S. Murthy, J. E. Thiemann, C. Coronelli and P. Sensi), 1198
Alaskan Volcano: Evidence of Two Sound Channels in the Polar Atmosphere from Infrasonic Observations of the Eruption of an (C. R. Wilson *et al.*), 163–5
Albany, N.Y. Condensation Nuclei: International Conference at (W. J. Megaw), 463
Albu, Austen. Memoirs of a New Man, *review*, 1017
Albumin Denaturation: Kinetics and Mechanism of (T. G. Ferris and S. Katz), 586–8
Albumin/Globulin Ratios in Mice: Electrophoretic Determination of (S. Klasky and Prof. M. J. Pickett), 1298–1300
Alcohol Plating Solutions: Dissociation of Sodium Carbonate and Sodium Sulphite in (W. Parker and W. Gullholmer), 1142
Alcohols: Primary Organic Radical formed in the Radiolysis of Aliphatic (R. A. Basson), 629–31
Production of Carbonyl Compounds by Tomato Fruit Tissue in the Presence of Aliphatic (Dr. D. F. Meigh *et al.*), 419
Aldrin and Benzene Hexachloride Residues by Gas Chromatography: Interference with the Determination of (D. F. Lee, J. Britton, B. Jeffcoat and R. F. Mitchell), 521
Alexander, Dr. A. F. O'D.: The Planet Uranus: History of Observation, Theory and Discovery, *review* by S. Weintroub, 346
Alexander, J. B.: Origin and Evolution of the Universe, *review*, 1346
Alford, Dr. T. C., *et al.*: Adenovirus Antibody and Antibody to 'T' Antigen (Neoantigen) Location in Gamma-globulin, 423
Algae: Gigartinine: a New Amino-acid in Red (K. Ito and Y. Hashimoto), 417
Preparation of Pure Blue-Green (M. P. Kraus), 310
Algorithm to assist in finding the Complete Sub-graphs of a Given Graph (Dr. A. R. Meetham), 105
Ali, M. I., *et al.*: Effect of Seed Dressing with 'Granosan' on the Prevalence of Fungi in the Root Zone of Cotton Plants, 1217
Alimentary Fats: Serum Cholesterol Levels in Alloxan Diabetic Rats after Loading with Various (B. Rudas), 320
Aliphatic Alcohols: Primary Organic Radical formed in the Radiolysis of (R. A. Basson), 629–31
Production of Carbonyl Compounds by Tomato Fruit Tissue in the Presence of (Dr. D. F. Meigh *et al.*), 419
Alivisatos, Prof. Spyridon G. A., Ungar, F., and Mourkides, G. A.: Incorporation of Histamine Ribonucleoside into Soluble Proteins, 187
Aliwal Shoal, South Africa: Age of the (Dr. A. N. Carter), 507
Alkali Halides in Water: Electrostatic Potential Model for the Solubility of the (M. Hacskaylo), 1035–7
Alkali Ions in a Model System driven by Water Flow: Transport of (J. Rastas *et al.*), 1152–4
Alkaline Electrolyte: Oxygen Reduction on Titanium Nitride in (Dr. J. Giner and L. Swette), 1291
Alkaline Phosphatase Activity in the Intestine of the Chick Embryo by Actinomycin *D*: Elevation of (Dr. R. D. Grey and Prof. F. Moog), 418
Alkaline Phosphatase: Intracellular Repressor of (Dr. S. W. Bowne, jun., *et al.*), 980
p-Alkoxy- and -Alkylthio-benzoic Acids: Strengths of (Dr. N. H. P. Smith), 186
Alkyl Halides: Criterion of Mechanism based on Optical Rotation and Rearrangement in Alkyl Groups during Formation of (Dr. W. Gerrard *et al.*), 740
Alkylating Agents in Mammalian Cells and Evidence for the Removal of Alkylated Groups from DNA: Mechanism of the Cytotoxic Action of (Dr. A. R. Crathorn and Dr. J. J. Roberts), 150–3
Alkylating Agents and Radiation on Murine Leukaemia Cells *in vitro*: Comparison of Direct and Indirect Effects of (Dr. G. J. Goldenberg), 427
-Alkylthio-benzoic Acids: Strengths of *p*-Alkoxy- and (Dr. N. H. P. Smith), 186
Allan, Dr. D., and Malkinson, M.: Spectrophotometric Detection and Measurement of Sensitizing Antibodies, 493–6
Allanson, Prof. J. T.: Information and Communication Theory (Electronic User Series), *review*, 570
Allen, Dr. R. J. L., Brook, M., Lister, Dr. R. B., Sim, Dr. A. K., and Warwick, M. H.: Metabolic Differences between Dietary Liquid Glucose and Sucrose, 1104
Allerton, Dr. Samuel E., and Perlmann, Dr G. E.: Optical Rotatory Dispersion of Phosvitin, 1089
Allogeneic Red Cells: Induction of Tolerance in Adult Mice to (Dr. J. S. Thompson *et al.*), 1155–7
Allogeneic Thymus: Suppression of Homograft Immunity in Chickens grafted *in ovo* with (Prof B. D. Janković and K. Isaković), 93
Allosteric Effects in Phosphorylase B: Spectroscopic Evidence of (S. Bresler *et al.*), 1262
Allosteric Model for Membrane Pumps: Simple (Dr. O. Jardetzky), 969
Allotypic γ-Globulins in Rabbits: Lack of Natural Tolerance to (Prof. P. G. H. Gell and Dr. A. S. Kelus), 766
Alloxan Diabetic Rats after Loading with Various Alimentary Fats: Serum Cholesterol Levels in (B. Rudas), 320
Alluvial Clays in the Western Gezira, Republic of the Sudan: Age of (M. A. J. Williams), 270
Alpen, Dr. E. L., and Johnston, M. E.: Deoxyribonucleic Acid Content of Mitotic Nuclei of Two Mouse Tumours, 715–7
Alpha Activation Cycle: Oculomotor Function and the (Dr. T. Mulholland and Dr C. R. Evans), 1278
Alpha- and Gamma-radiation on an Enzyme: Comparison of the Effect of (Dr. P. M. Kopp, Dr J. F. Read and Prof. A. Charlesby), 959
Alpha Motoneurones to Direct Electrical Stimulation during Desynchronized Sleep: Response of (A. R. Morrison and O. Pompeiano), 636
Altitude: Shock Wave from a Release of Gas at 110 km (L. M. Sheppard), 59
Altman, Dr. K. I., *et al.*: Effect of Thorazine (Chlorpromazine) on Collagen Metabolism, 880
Altman, Dr. Samuel P.: Orbital Hodograph Analysis, *review* by D. G. King-Hele, 1343
Alumina: Gas–Solid Chromatographic Separation of Atmospheric Gases on Activated (R. L. Hoffmann *et al.*), 965
Aluminium: Stress-corrosion Cracking of (A. J. Jacobs), 403
Alveolar Deposition of Aerosols on the Moon and in Outer Space (Dr. J. M. Beeckmans), 208
Ambient or Self-generated Noise: Obstacle Detection using (Dr. J. P. Wilson), 218
Ambiplasma: Proposed Search for Antimatter among Hydrogen-like Atoms in the (Prof. W. A. Barker *et al.*), 1383
Amborski, Dr. Grace F., *et al.*: Structure Development in Aggregens, 1047–9
Ambrus, Prof. J. L., and Strandstrom, H. V.: Susceptibility of Old World Monkeys to Yaba Virus, 876
America. Atomic Energy in Latin, 223
American Libraries: Benjamin Franklin and Eighteenth-Century (Miss M. B. Korty), *review* by Dr. F. N. L. Poynter, 234
American Rock Names, 1222
Amethyst and Citrine Quartz: Paramagnetic Resonance Centres in (D. R. Hutton and G. J. Troup), 621
Amide Groups: Electrophoretic Mobilities of Peptides on Paper and their Use in the Determination of (R. E. Offord), 591–3
L-Amino-acid Oxidase: Rate-determining Step in the Action of (D. J. Triggle and J. F. Moran), 307
Amino-acid Recycling: Use of Carbon-14-labelled Arginine to measure the Catabolic Rate of Serum and Liver Proteins and the Extent of (Dr. J. M. L. Stephen and Prof. J. C. Waterlow), 978–80
Amino-acid in Red Algae: Gigartinine: a New (K. Ito and Y. Hashimoto), 417
Amino-acid Residues: Stereochemical Code of (Prof. A. M. Liquori *et al.*), 1039–41
Amino-acid Sequence of Peptides: Mass Spectrometric Determination of the (Prof. M. M. Shemyakin *et al.*), 361–6
Amino-acids in the Germination of Bacterial Spores by Subtilisin: Role of (Dr G. W. Gould and W. L. King), 1431
Amino-acids in Sugar Beet: Translocation of (K. W. Joy and A. J. Antcliff), 210
Amino-acyl-sRibonucleic Acid Binding Sites on Ribosomes: Polypeptidyl-sRNA and (M. S. Bretscher and Dr. K. A. Marcker), 380–4
Aminoacyl Transfer Reaction in Protein Synthesis: Monovalent Cation Requirement for the (H. Levine, M. R. Trindle and Prof K. Moldave), 1302
γ-Aminobutyric Acid an Inhibitory Transmitter? Is (Prof. K. Krnjević and Dr. S. Schwartz), 1372–4
Amir, S. M., Barker, Dr. S. A., Butt, W. R., and Crooke, Dr. A. C.: Gonadotrophin-inhibiting Action of Certain Carbohydrates, 975
Amir, S. M., Barker, Dr. S. A., Butt, W. R., Crooke, Dr. A. C., and Davies, A. G.: Administration of *N*-Acetyl-D-mannosamine to Mammals, 976
Ammonia in the Atmospheric Corrosion of Mild Steel: Role of (Prof. T. K. Ross and Dr B. G. Callaghan), 25
Ammonium Perchlorate: Thermal Decomposition of Irradiated Orthorhombic (Dr. P. J. Herley and Dr. P. W. Levy), 1287
Amoebae Cytoplasmic Deoxyribonucleic Acid-containing Bodies in (D. R. Wolstenholme), 652
Amoebae for the Study of their Nuclear Division: Culture Method of growing *Entamoeba histolytica* and Other Anaerobic (J. P. Dubey and S. R. Das), 992
Amoroso, Prof. E. C.: Fertilization, *review*, 1344
Amphetamine Excitatory Response: Role of Catecholamines in the (Dr. A. Randrup and Dr. I. Munkvad), 540
Amphibia. Presence of Adenosine Triphosphate in the Skin Venom of (Prof. M. Vialli and L. Bolognani), 1324
Amphibians: Ultrastructural Transport Mechanism of Messenger Ribonucleic Acid in the Young Oocytes of (T. Takamoto), 772
Amplitudes from *Longshot* at Australian Stations: *P* (J. Cleary), 954
α-Amylase Formation by *Bacillus subtilis*: Characteristics of (Dr. G. Coleman and M. A. Grant), 306
Amyloid Filaments: Periodic Crossbanding in (Dr. H.-J. Merker *et al.*), 1401
Anabolic Androgens on Tissue Replacement in the Ear of the Rabbit: Effect of (Prof. J. Joseph and Dr. M. Dyson), 193
Anaerobic Amoebae for the Study of their Nuclear Division: Culture Method of growing *Entamoeba histolytica* and Other (J. P. Dubey and S. R. Das), 992
Anaerobic Metabolism: Adrenergic Beta-receptor Blockade and (Dr. C. Furberg), 888
Anaerobic Spermatozoan Metabolism: Metabolic End-products of (Dr. C. N. Graves, Dr. J. R. Lodge and Dr. G. W. Salisbury), 308
Analgesic Substances: Arylacethydroxamic Acids: a New Class of Potent Non-steroid Anti-inflammatory and (Prof. N. P. Buu-Hoï *et al.*), 752
Analysis: Elementary (R. F. McCoart *et al.*), *review* by Dr. R. L. Perry, 18
Analysis of the Major Constituents of Fuel Gases by Gas Chromatography (R. A. Cross), 409
Anaphylactic Shock and the Secretion of Adrenal 17-Hydroxycorticosteroid in the Dog (Prof. T. Suzuki, K. Hirai, K. Otsuka, H. Matsui and S. Ohukuzi), 1185
Andersen, Dr P., Andersson, S. A., and Lomo, T.: Patterns of Spontaneous Rhythmic Activity within Various Thalamic Nuclei, 888
Anderson, Dr. G., *et al.*: Extraction of Organic Matter from Soils by means of Ultrasonic Dispersion in Aqueous Acetylacetone, 1430
Anderson, I. Ö., and Brune, D.: Independent Fission-fields of Caesium-134, 618
Andersson, Olle: Stress Relaxation of Bitumen and Bituminous Mixtures, 402
Andersson, S. A., *et al.*: Patterns of Spontaneous Rhythmic Activity within Various Thalamic Nuclei, 888
Andersson, Dr. Sten, and Wadsley, Dr. A. D.: Crystallographic Shear and Diffusion Paths in Certain Higher Oxides of Niobium, Tungsten, Molybdenum and Titanium, 581–3
Androgens on Tissue Replacement in the Ear of the Rabbit: Effect of Anabolic (Prof. J. Joseph and Dr. M. Dyson), 193
Anesthesiology: Foundations of (A. Faulconer and T. E. Keys), Two Volumes, *review* by Prof. W. W. Mushin, 685
Anghileri, Dr. L. J.: Uptake of Iodine-131-labelled Atabrine by Ehrlich Ascites Tumour and by Sarcoma S-180 *BALB*, 878
Angiosperms: Continental Drift, Mesozoic Continents and the Migrations of the (Dr. R. Melville), 116–20
Nuclear Variation between Diploid (Dr. H. Rees *et al.*), 828–30
Angiotensin Formation in response to Carotic Occlusion in the Dog: Increased (Dr. R. L. Hodge, Dr. R. D. Lowe and Prof. J. R. Vane), 491–3
Angiotensin: Response of Pineal Sympathetic Nerve Processes and Endings to (Dr. N. M. Panagiotis and Prof G. F. Hungerford), 374–6
Angiotensin, Tritiated: Preparation and Purification (Dr. R. R. Smeby *et al.*), 1193
Anhydroformaldehyde Aniline–Insulin Mixture: Oral Hypoglycaemic Activity of an (Dr. J. K. Wales *et al.*), 88
Aniline–Insulin Mixture: Oral Hypoglycaemic Activity of an Anhydroformaldehyde (Dr. J. K. Wales *et al.*), 88
Animal Experimentation. Methods of (edited Dr. W. I. Gay), Two Volumes, *review* by Dr. W. Lane-Petter, 120
Animals: Water Content in the Tissues of Desert (Prof. W. Sokolov), 545
Anisotropy in the Charged Primary Cosmic Radiation: Evidence for a Two-way Sidereal (R. M. Jacklyn), 690–3
Annear, D. I.: Recoveries of Bacteria after Drying *in vacuo* at a Bath Temperature of 100° C, 761
Announcements, 5, 114, 225, 339, 451, 559, 674, 790, 902, 1012, 1116, 1224, 1335

Anomalous Reflectivity of Shock Waves (I. N. Court and W. R. Mallory), 625
Anomuran and Brachyuran Crustaceans to High-speed Centrifugation: Responses of some (Dr. W. Abbott and C. E. Dawson), 1320
Anopheles gambiae: Light-on and Light-off Effects on the Circadian Flight Acitivity in the Mosquito (M. D. R. Jones et *al.*), 871
Antarctic: Bispecific Chimerid Sponges from the (F. J. Little, jun.), 436–8
Antarctic Bottom Current on the Bermuda Rise: Sediment Transport by the (Prof B. C. Heezen et *al*), 611
Antarctica: Noctilucent Clouds observed in (R. J Francis et *al*), 398
Antarctica: Soils and Micro-organisms from Mount Erebus (F. C. Ugolini and Prof. R. L. Starkey), 440
Antcliff, A. J., and Joy, K. W.: Translocation of Amino-acids in Sugar Beet, 210
Anthocyanins in the Seed Coats of the Phaseoleae: Ecological Significance of (Dr. W. R. Stanton and B Je Francis), 970
Anthracene Crystals: Effect of Temperature on the Triplet–Triplet Annihilation Rate in (G. F. Moore), 1170
Anthracene Triplet: Effect of Deuterium Substitution on Radiationless Decay of (Dr. A. Beckett), 410
Anthranilic Acid in Cultures of the Basidiomycete *S-hizophyllum commune*: Identification of 1-(o-Carboxyphenylamino)-1-deoxyribulose and (E. Epstein), 855
Antibiotic and Narrowing Factor: Citrinin—a Fungistatic (Dr. P. M. Robinson and Dr D. Park), 883
Antibiotic 'Nystatin': An Enrichment Method for Auxotrophic Yeast Mutants using the (Prof. R. Snow), 206
Antibiotic Production in the Dacrymycetaceae (Dr. M. N. Schwalb), 311
Antibiotics on Bacterial Morphologic Changes induced by Penicillin G. Inhibitory Effects of Other (T.-W. Chang and Dr. L. Weinstein), 763–5
Antibodies, with the DNA Molecule: Interactions of Protein (Dr. A. M. Poverenny et *al.*), 1297
Antibodies in Monkeys bearing Tumours induced by Rous Sarcoma Virus: Complement-fixing (M. J. Casey et *al*), 1417
Antibodies from Rabbit Antisera using Acetone-precipitated Soluble Proteins: Elimination of Non-specific (B. Schmidt, Y. Hosokawa and D. Hartmann), 32
Antibodies: Spectrophotometric Detection and Measurement of Sensitizing (Dr. D. Allan and M. Malkinson), 493–6
Antibodies to Synthetic Corticotrophin (Dr. J. P. Felber, S. H. J. Ashcroft, A. Villanueva and A. Yannotti), 654
Antibody Activity: Identification of Two Fowl β Macroglobulins with Precipitating (J. Carey et *al*), 30–2
Antibody Formation and Experimentally Induced Chimerism in Very Young Rabbits (Chi-Tao Chou, S. Dubiski and B. Cinader), 34–6
Antibody Production in Bursectomized Chickens given Repeated Injections of Antigen (Prof. B. D. Janković and Dr. K. Isaković), 202
Antibody to 'T' Antigen (Neoantigen) Location in Gamma-globulin: Adenovirus Antibody and (Dr. A. C. Hollinshead et *al.*), 423
Antibody Variation: Origin of (Dr. S. Brenner and Dr C Milstein), 242
Antidiuretic and Vasopressor Activity in Rat Posterior Pituitaries on Incubation *in vitro*: Dissociation between (E. van Kammen and Prof. D. De Wied), 93
Antifertility Agents with Hypocholesteraemic Activity: New Class of Orally Effective (Dr. H. A. DeWald et *al.*), 538
Antifungal Compounds in Apple Fruit infected with *Sclerotinia fructigena* (Dr. C. H. Fawcett and Dr D. M. Spencer), 548
Antigen: Antibody Production in Bursectomized Chickens given Repeated Injections of (Prof. B. D. Janković and Dr. K. Isaković), 202
Antigen by *Mycoplasma pneumoniae in vitro* and *in vivo*: Failure to Demonstrate Blocking of I (Dr. T. Feizi and Dr. J. H. Darrell), 1159
Antigen (Neoantigen) Location in Gamma-globulin: Adenovirus Antibody and Antibody to 'T' (Dr A C. Hollinshead et *al.*), 423
Antigenic Constituents of Human Cortical Grey Matter (Dr. P. C. Rajam and Dr. S. Bogoch), 1200
Antigens in Cattle infected with *Babesia bigemina* or *B. argentina*: Circulating (D. F. Mahoney), 422
Antigens from Human Brain: Organ Specificity of Heat-stable (Dr. P. C. Rajam et *al.*), 1201
Anti-inflammatory and Analgesic Substances: Arylacethydroxamic Acids: a New Class of Potent Non-Steroid (Prof. N. P. Buu-Hoï et *al.*), 752
Anti-matter Content of the Tunguska Meteor (R. V. Gentry), 1071
Antimatter among Hydrogen-like Atoms in the Ambiplasma: Proposed Search for (Prof. W. A. Barker, F. A. Costanzi, J. B. Drahmann, W. Honzik, D. Monohan, T. Simko and M. Williams, 1383
Antirabies One-day-egg Vaccine: Simplified Course of Immunization for the (Prof K. Yoshino et *al.*), 542–4
Anti-ribonucleic Acid Factors in the Sera of Germ-free Animals (Prof. J. Panijel, P. Cayeux, E. Sacquet and H. Charlier), 94–6
Antisera using Acetone-precipitated Soluble Proteins: Elimination of Non-specific Antibodies from Rabbit (B. Schmidt et *al.*), 32
Antitumour Activity of *N*-Hydroxyurethane (Miss M. A. Hahn, Mrs. C. C. Botkin and Dr. R. H. Adamson), 984
Antitumour Agent isolated from a *Streptomyces*: Alanosine, a New Antiviral and (Y. K. S. Murthy et *al.*), 1198
Anti-Viral Activity of Azathymidine and Uracil Methyl Sulphone (Dr. L. Sekely and Prof. W. H. Prusoff), 1260
Antiviral and Antitumour Agent isolated from a *Streptomyces*: Alanosine, a New (Y. K. S Murthy et *al.*), 1198
Aoki, Dr. Tsuyoshi: Evidence for the Discharge of Cholinesterase into Canine Eccrine Sweat, 886
Aorticopulmonary Glomus Tissue in the Cat (Dr. H. Coleridge, Dr. J. C. G. Coleridge and Dr. A. Howe), 1187
Apatitic Calcium Phosphates: Infra-red Determination of the Percentage of Crystallinity in (J. D. Termine and Dr A. S. Posner), 268–70
Aphids: Supercooling in the Cornicle Wax of (Dr. J. S. Edwards), 73
Apices cultured *in vitro*: Flower (Dr. J. Blake), 990
Apolysis in Arthropod Moulting Cycles (P. M. Jenkin and Prof. H. E. Hinton), 871
Apparatus for Continuous Dielectric-medium Separation of Mineral Grains (R. H. Verschure and L. Ijlst), 619
Apparent Organic Peroxide ('Pro-blue') in Mice given an Oral Contraceptive: Diminution in (V. J. Horgan and J. St. L. Philpot), 597
Apple Fruit infected with *Sclerotinia fructigena*: Antifungal Compounds in (Dr. C. H Fawcett and Dr. D. M. Spencer), 548
Apple Seeds: Identification of Gibberellins A_3 and A_7 in Immature (F. G. Dennis, jun., and J P. Nitsch), 781
Appointments, 6, 225, 339, 451, 559, 674, 790, 902, 1116, 1224, 1335
Approximation. JWKB (N. Froman and P. O. Froman), *review* by Dr. D. W. Wood, 798
Apter, Dr. Michael J : Cybernetics and Development, *review* by Prof. C. H. Waddington, 566
Aqueous Systems containing Bile Salt, Lecithin, and Cholesterol: Ternary and Quaternary (D. M. Small et *al.*), 816–8
Arachnida: Esterase Activity in the (P. M. Pollak), 546
Arai, Kazuji, et *al.*: Simplified Course of Immunization for the Antirabies One-day-egg Vaccine, 542–4
Aramanovich, I. G., et *al.*: (for other authors) *see*: Mathematical Analysis: Differentiation and Integration, *review* by Dr. R. L. Perry, 238

Deoxyribonucleic Acid. *In vivo* Complex Formation of Actinomycin D and (Dr. F F. Becker et *al.*), 84
Haemagglutinating Properties of (L Leahu), 421
Mechanism of the Cytotoxic Action of Alkylating Agents in Mammalian Cells and Evidence for the Removal of Alkylated Groups from (Dr. A. R Crathorn and Dr. J. J. Roberts), 150–3
Effect of Total Dose, Dose Rate and Time of Irradiation on Synthesis of (L. O. Chang et *al.*), 300–2
Deoxyribonucleic Acid-containing Bodies in Amoebae: Cytoplasmic (D. R. Wolstenholme), 652
Deoxyribonucleic Acid on Incubation in Agar: Discriminating Power of Rodent (Dr. A McLaren and Dr. P. M. B. Walker), 486–90
Deoxyribonucleic Acid Components in Insect Cells as revealed by Electron Microscopy: Intranucleolar (Dr J. Jacob), 36–8
Deoxyribonucleic Acid Content of Mitotic Nuclei of Two Mouse Tumours (Dr. E. L. Alpen and M. E. Johnston), 715–7
Deoxyribonucleic Acid Molecule: Interactions of Protein (Antibodies) with the (Dr. A. M. Poverenny et *al.*), 1297
Deoxyribonucleic Acid from Rat Liver Cells: Comparison of Physicochemical Properties of Mitochondrial and Nuclear (T. B. Kazakova and K. A Markosiah), 79
DNA-Protein in the Mixed Leucocyte Reaction *in vitro*: Efficiency of Scintillation Counting of Tritium Labelled (Dr. J. F. Moorhead and Dr. W. McFarland), 1157–9
Deoxyribonucleic Acid Replication in Bacteria: Requirement for RNA Synthesis for (Dr. C. O. Doudney), 39–41
Deoxyribonucleic Acid Solutions. Turbulent-flow Properties of (Dr. J. W. Hoyt), 170
Deoxyribonucleic Acid Synthesis: Time of Chiasma Formation in Relation to the Time of (Dr. S. A. Henderson), 1043–7
Deoxyribonucleic Acid Synthesis Time of Erythropoietic and Granulopoietic Cells in Human Beings (P. Stryckmans, Dr. E. P. Cronkite, J. Fache, T. M. Fliedner and J. Ramos), 717–20
Deoxyribonucleic Acid to Ultra-violet Light: Sensitivity of the Phage and Complementary Strands of the Replicative Form of Phage φX 174 (B. N. Iliashenko), 430
Deoxyribonucleic Acid from Various Organs on Irradiated Mice: Recovery Effect of Heterologous (Dr. N Savković et *al.*), 1179
Deoxyribonucleic Acids Dissimilarity between Human and Bacterial (Prof. J. De Ley and I. W. Park), 1002
Deposition of Aerosols on the Moon and in Outer Space: Alveolar (Dr. J. M. Beeckmans), 208
Depressor Response to Small Doses of Adrenaline: Cholinergic Mechanism of (Dr. L. P. McCarty and Dr. M. B. Chenoweth), 750
Derruau, M.: Précis de Géomorphologie, Fourth Edition, *review* by Prof. T. N. George, 1018
Dervichian, D. G.: Ternary and Quaternary Aqueous Systems containing Bile Salt, Lecithin, and Cholesterol, 816–8
Desalination—in Perspective: Sea Water (Dr. E. Glueckauf), 1227–30
Desalination of Sea Water: Parliament in Britain, 113
de Santis, P., et *al.* Stereochemical Code of Amino-acid Residues: the Molecular Conformation of Gramicidine S, 1039–41
Desert Animals: Water Content in the Tissues of (Prof. W. Sokolov), 54
Desmodus rotundus: Plasminogen Activator in Saliva of the Vampire Bat (C. Hawkey), 434
Desynchronized Sleep: Response of Alpha Motoneurones to Direct Electrical Stimulation during (A. R. Morrison and O Pompeiano), 636
Detector for Gas-phase Titration: Ionization (T. L. Foldvari et *al.*), 294–6
Detector with Helium and Neon as the Carrier Gases: Sensitivity to Oxygen of an Ionization (P. J. Bourke and R. W Dawson), 409
Deuterium Substitution on Radiation-less Decay of Anthracene Triplet: Effect of (Dr. A. Beckett), 410
Deuteron Stripping Reactions: Tanifuji–Butler Model for (Dr. C. A Pearson and Dr. J. M. Bang), 577
Deutsch, Edna W., and Hansch, Prof. C : Dependence of Relative Sweetness on Hydrophobic Bonding, 75
Development Assistance Committee (DAC) of the O.E.C.D.: Who Gives Most? 447
Development: Cybernetics and (Dr. M. J. Apter), *review* by Prof. C. H. Waddington, 566
Development of Insects: Relation of Temperature to the Duration of the (M. D. Mountford), 993
Developmental Stages of *Theileria parva in vitro* at High Temperature Transition of (Dr. L. Hulliger et *al.*), 328
de Visme, G.: Logique Binaire et Commutation, *review*, 1342
Devonian Fishes from Kashmir, India (V. J. Gupta and Dr. R. H. Denison), 177
DeWald, Dr. Horace A., Bird, Dr. O D., Rodney, G., Kaump, Dr. D. H., and Black, Dr. M. L.: New Class of Orally Effective Antifertility Agents with Hypocholesteraemic Activity, 538
Dew-Hughes, Dr. David: Materials Used in Semiconducting Devices, *review*, 461
De Wied, Prof. D., and van Kammen, E.: Dissociation between Antidiuretic and Vasopressor Activity in Rat Posterior Pituitaries on Incubation *in vitro*, 93
Dexamphetamine on Activity of Rats in an Unfamiliar Environment: Combined Effects of Chlordiazepoxide and (Dr. R Rushton and Dr. H Steinberg), 1312
Diabetic Rats after Loading with Various Alimentary Fats Serum Cholesterol Levels in Alloxan (B Rudas), 320
Dialysable Constituent of Recalcified Human Plasma Clots and Gluconate: *In vivo* Fibrinolysis with a (Prof. P. H. Kopper), 43
Diaminopyrene-*p*-chloranil and Related Molecular Complexes Polymorphic Forms of the (Dr. Y. Matsunaga), 183
Diamond: Birefringence of (Prof. S. Tolansky), 158–60
Diamonds. Electron Spin Resonance of Nickel in Synthetic (Prof. J. H. N. Loubser and W. P. van Ryneveld), 517
Pyrrhotite: a Common Inclusion in South African (W. E. Sharp), 402
Diaphorase in Foetal, Newborn and Adult Cattle: Reduced Diphosphopyridine Nucleotide-dependent (Dr. J. E. Smith and Dr. E Beutler), 756
Diatoms Free from Bacteria? Are Pelagic (Dr. M. R. Droop and K. C. R. Elson), 1096
Dick, Christine M , and Hutchinson, Dr. S. A.: Biological Activity of Volatile Fungal Metabolites, 868
Dicke, Prof. R. H , and Peebles, Prof. P. J. E.: Origin of the Microwave Radio Background, 574
Dictionary of Nuclear Physics and Nuclear Chemistry: Second Edition (edited by H. Rau), *review* by Dr. J. B. Sykes, 462
Dielectric-medium Separation of Mineral Grains: Apparatus for Continuous (R. H. Verschure and L. Ijlst), 619
Dietetics: Human Nutrition and (S. Davidson and R. Passmore), Third Edition, *review* by Dr. A. M. Copping, 1127
Di-ethyl Acetal: Reactions of the Hydroxyl Radical in the Radiolysis of Aqueous Solutions of (Dr. R. A. Basson and P. M. Champion), 1398
Diffracted Neutrons with a Piezoelectric Crystal: Modulation of (Prof. T. F. Parkinson and M. W. Moyer), 400
Diffraction: Coherence in Optics (Prof. M. Françon), *review* by Prof. D. Gabor, 1123
Diffraction Studies of Double Helical Ribonucleic Acid: X-ray (Dr. S. Arnott et *al*), 227–32
Diffusion-exchange Respirometer using the Carbon Dioxide Electrode (Dr. C. R Jensen, Dr. S. D. Van Gundy and Dr. L. H. Stolzy), 608–10
Diffusion in Microcapillaries: Flux Relations for (J. B. Butt and R N. Foster), 284
Diffusion in Mouse and Rat Erythrocytes Facilitated (B. Ospina and Prof. F. R. Hunter), 851
Diffusion Paths in Certain Higher Oxides of Niobium, Tungsten, Molybdenum and Titanium: Crystallographic Shear and (Dr. S. Andersson and Dr. A. D. Wadsley), 581–3
Diffusion of Triplet Excitons produced by Ionizing Radiation in Aromatic Materials (Dr. R. Voltz, Dr. H. Dupont and Dr. T. A. King), 405
Dijkgraaf, C., van Heel, J P. C., and Rousseau, J. P. G.: Electronic Transitions in Hexachloro-co-ordinated Titanium and Chromium, 185

3,4-Dimethoxyphenylacetic Acid in Urines of Normal and Schizophrenic Individuals: Occurrence of (Dr. F. A. Kuehl, jun., R. E. Ormond and W. J. A. VandenHeuvel), 606–8
3,4-Dimethoxyphenylethylamine in Schizophrenia (C. H. Williams, Prof. J. G. Gibson and W. O. McCormick), 1195
Dimethylalloxazine as an Electron Donor and Acceptor (Dr. Y. Matsunaga), 182
7,12-Dimethylbenz(*a*)anthracene in New-born and Adult Swiss Mice: Toxic Effects of (Dr. B. Toth and Prof. P. Shulak), 428
9,10-Dimethyl-1,2-benzanthracene in Rats: Liver Injury and the Prevention of Massive Adrenal Necrosis from (Dr. D. N. Wheatley *et al.*), 387–9
4,4′-Dimethylbenzophenone: Radiothermoluminescence of (N. S. Marans *et al.*), 1176
N,*N*-Dimethyl-*p*-methoxy-L-phenylalanyl Analogue of Puromycin: Release of Peptide Chains from Rat-liver Polysomes by the (A. O. Hawtrey and Miss S. I. Bredron), 187–9
2,12-Dimethyl-3,7,11,17-Tetraazabicyclo (11.3.1) Heptadeca-1 (17),2,11,13,15-Pentaene: Nickel (II) Complexes of the Tetradentate Macrocycle (J. L. Karn and Prof. D. H. Busch), 160–2
Dingle, Prof. Herbert: Basic Concepts of Measurement, *review*, 15
Dingle, Dr J. T., *et al* · Effect of Cortisol on the Synthesis of Chondroitin Sulphate by Embryonic Cartilage, 83
Dinosaur Bone: Cells, Collagen Fibrils and Vessels in (R. Pawlicki *et al.*), 655–7
Dintenfass, L., and Rozenberg, M.C.: Platelet Aggregation in the Variable-frequency Thromboviscometer, 525–7
Dintenfass, Leopold: Viscometry of Human Blood for Shear Rates of 0–100,000 sec^{-1}, 632
Diphosphopyridine Nucleotide-dependent Diaphorase in Foetal, Newborn and Adult Cattle: Reduced (Dr. J. E. Smith and Dr. E. Beutler), 756
Diphyllobothrium Plerocercoids in the Trout *Salmo trutta* L. of Llyn Padarn, Caernarvonshire: Decline in the Occurrence of (A. M. Powell and Dr. J. C. Chubb), 439
Dipicolinate on the Heat Denaturation of Proteins: Effect of (Y. Mishiro and M. Ochi), 1190
Diploid Angiosperms. Nuclear Variation between (Dr. H. Rees *et al.*), 828–30
Dipterocarp Trees of Brunei State: Manual of the (Dr. P. S. Ashton), *review* by L. L. Forman; 567
Disarmament Problems. Pugwash after Pugwash, 1330
Pugwash in Poland, 1331
Discharge: Changes in Loss Tangent of Polythene subjected to Partial (A. W. Stannett and R. A. Mackenzie), 626
Discharges: Pinched Lightning (Dr. C. E. R. Bruce), 62
Discrete Radio Sources in the 20–40 Mc/s Range: Spectra of Nine (D. A. Guidice), 57–9
Discriminating Power of Rodent Deoxyribonucleic Acid on Incubation in Agar (Dr. A. McLaren and Dr. P. M. B. Walker), 486–90
Diseases of Lower Vertebrates: Principal (H. Reichenbach-Klinke and E. Elkan), *review* by Prof. H. G. Lamont, 1126
Disks: Isolation of a Chondroitin Sulphate Protein Complex from Bovine Intervertebral (Dr D. A. Lowther and E. Baxter), 595–7
Dislocation Loops in Beryllium Oxide irradiated at High Temperatures· Interstitial (R. C Rau), 71
Dislocation Zone in Central Malawi: Major East-north-east (Dr. K. Bloomfield), 612–4
Distillation (edited by E. S. Perry and A. Weissberger) Second Revised Edition, (Technique of Organic Chemistry, Vol. 4), *review* by Dr. M. G. Royston, 236
Distribution of Sulphides in Peat Soils: Improved Method of demonstrating the (C. Urquhart), 550
Disulphide Exchange: New Assay of the Ribonuclease-reactivating Enzyme based on (P. Venetianer), 643
Disulphides. Rearrangement of *Bis*(*o*-thiocarbonyl) (B. S. Shasha *et al.*), 965
Ditkin, V. A., and Prudnikov, A. P.: Integral Transforms and Operational Calculus, *review* by Dr. M. A. Jaswon, 235
Diurnal Variation in Organismic Response to Very Weak Gamma Radiation (Prof. F. A. Brown, jun., Y. H. Park and J. R. Zeno), 830–3

Methods in Zone (J. R. Sargent), *review* by Dr. E. R. Skinner, 568
Electrophoretic Determination of Albumin/Globulin Ratios in Mice (S. Klasky and Prof. M. J. Pickett), 1298–1300
Electrophoretic Fractionation of Heat-denatured Eucollagen (D. J. Carmichael), 861
Electrophoretic Fractions: Human Serum Enzymes in (V. B. Kambli and R. W. P. Master), 532
Electrophoretic Heterogeneity of Erythrocyte and Leucocyte Glucose-6-phosphate Dehydrogenase in Italians from Various Ethnic Groups (A. Bonsignore, Prof. G. Fornaini, G. Leoncini and A. Fantoni), 876
Electrophoretic Mobilities of Peptides on Paper and their Use in the Determination of Amide Groups (R. E. Offord), 591–3
Electrophoretic Separation of Serum Acid Phosphatase Isoenzymes in Gaucher's Disease, Prostatic Carcinoma and Multiple Myeloma (Dr. A. F. Goldberg, Dr. K. Takakura and Dr. R. L. Rosenthal), 41–3
Electroretinographic Measurements of its Effect on Photopic Sensitivity in Chicks: Provitamin A_5: (E. Auerbach et *al.*), 77
Electrostatic Fields: Some Responses of *Drosophila* to Weak Magnetic and (H. D. Picton), 303
Electrostatic Fields on Seed Germination: Influence of (G. H. Sidaway), 303
Electrostatic Potential Model for the Solubility of the Alkali Halides in Water (M. Hacskaylo), 1035–7
Element Concentrations in the Sea off South Africa: Trace (Prof. E. C. Leisegang and M. J. Orren), 1166
Elements: Nomenclature of (Dr. R. Shuttleworth), 1178
Nomenclature of Metallic (Dr. A. Wolfenden), 632
Eleutherodactylus martinicensis: Spontaneous Movements in the Embryo of (Dr. A. Hughes), 51–3
Eleven-month "Embryonic Diapause" in a Marsupial (P. J. Berger), 435
Elimination Reactions in Free Radicals produced by OH Addition to Hydroxybenzenes: Pulse Radiolysis Investigations of Unimolecular (Dr. G. E. Adams et *al.*), 293
Elithorn, Dr. A., Jagoe, J. R., and Lee, Dr. D. N.: Simulation of a Perceptual Problem-solving Skill, 1029–31
Elkan, E., and Reichenbach-Klinke, H.: Principal Diseases of Lower Vertebrates, *review* by H. G. Lamont, 1126
Elliot, Prof. H.: Cosmic Rays, *review*, 797
Elliot, Marjorie W., et *al.*: Breast Cancer in a Tree Shrew (*Tupaia glis*), 1105
Elliot, Orville S., Elliot, M. W., and Lisco, Dr. H.: Breast Cancer in a Tree Shrew (*Tupaia glis*), 1105
Ellis, Brian. Basic Concepts of Measurement, *review* by Prof. H. Dingle, 15
Ellis, G. P.: Modern Textbook of Organic Chemistry, *review* by Dr. R. D. H. Murray, 1344
Ellis, Prof. G. R. A., and McCulloch, P. M.: Frequency Splitting of Solar Radio Bursts, 1070
Ellis, Dr. Roy E., and Berry, Dr. R. J.: A Fast-neutron Source for Radiotherapy, 267
Ellis, Dr. R. J.: Sulphur Metabolism the Usefulness of *N*-Ethylmaleimide, 1266–8
Elongation of Rat Tail Tendon: Effect of Peroxides on the Hydration (Dr. J. Pospíšilová), 536
Elson, K. G. R., and Droop, Dr. M. R.: Are Pelagic Diatoms Free from Bacteria? 1096
Embrittlement of Stainless Steel irradiated in Fast Fluxes: High-temperature (A. S. Fraser et *al.*), 291
Embryo by Actinomycin *D*: Elevation of Alkaline Phosphatase Activity in the Intestine of the Chick (Dr. R. D. Grey and Prof. F. Moog), 418
Embryo of *Eleutherodactylus martinicensis*: Spontaneous Movements in the (Dr. A. Hughes), 51–3
Embryology of the Ovary and Testis: *Homo sapiens* and *Macaca mulatta* (Dr. G. van Wagenen and Dr. M. E. Simpson), *review*, 1127
Embryonic and Adult Tissue: Effect of Magnetic Fields on the Respiration of Malignant, (Prof. J. C. Fardon et *al.*), 433
Embryonic Cartilage: Effect of Cortisol on the Synthesis of Chondroitin Sulphate by (Dr. A. J. Barrett et *al*), 83
"Embryonic Diapause" in a Marsupial: Eleven-month (P. J. Berger), 435
Emergency Purifier of Sea Water: Osmotic (K. Popper et *al.*), 297
Emigration of Doctors: Over the Rainbow, 1114, Who Stays Home? 1329
Emission from Galactic OH: Determination of Direction, Frequency and Polarization of Radio (Dr. A. H. Cook), 503
Emission of Venus at 3 cm and the Solar Activity: Radio (V. Letfus), 176
β-Emitting Isotopes: Simple Device for the Scintillation Counting of Aqueous Solutions of Calcium-45 and other (Dr. B. F. Sansom and P. J. Taylor), 626
Endothelium and Smooth Muscle to the Internal Elastic Membrane of the Major Arterial Circle of the Iris of Rabbits: Extrusion of ATPase Activity from Pinocytotic Vesicles of Abutting (Dr. C. A. Santos-Buch), 600–2
Endotoxin in Cultured Leucocytes: Cellular Localization of Carbon-14 (J. J. Oppenheim and S. M. Wolff), 767
Endotoxin-enhanced Host Resistance: Reversal by Kinetin Riboside (R. W. I. Kessel and Prof. W. Braun), 1001
Endroczi, E., and Lissák, K.: Neuroendrocrine Control of Adaptation, *review* by Dr. E. T. Bell, 568
Energy Losses from Vibrating Neutron Stars: Neutrino (C. J. Hansen), 1069
Energy Nuclear Reactions: High (Dr. A. B. Clegg), *review* by C. J. Batty, 16
Energy on the Reactivity of Methylene: Effect of Excess (R. S. B. Johnstone and R. P. Wayne), 1396
Engelmann, R. J., and Perkins, R. W.: Snow and Rain Washout Coefficients for Process Plant Radioiodine Vapour, 61
Engineering: Centres for, 449
Social History of (Prof. W. H. B. Armytage), Second Edition, *review* by Prof. B. Williams, 1341
Synchronized Training, 1332
Ultrasonic (Prof. J. R. Frederick), *review* by Dr. R. W. B. Stephens, 802
Engineering Aspects of Non-Newtonian Flow: Some (Dr. J. Harris), 579–81
Engineers: *Project* for, 4
Engineers by Television, 112
England: Strontium : Calcium Ratio in Tourmalines from South-west (Dr. G. M. Power), 1072
England and Wales: Seleniferous Soils in Parts of (Prof. J. S. Webb et *al.*), 327
Englishmen? Forty Million, Land and Human Population, 1007
Enneacarbonyl Iron (M. H. Chisholm et *al.*), 67
Enoplus communis: Chemical Nature of the Pigment Spots of (N. A. Croll), 859
Entamoeba histolytica and Other Anaerobic Amoebae for the Study of their Nuclear Division: Culture Method of growing (J. P. Dubey and S. R. Das), 992
Enterobacteriaceae: D-Glucarate Catabolism by Pseudomonadaceae and (Dr. P. W. Trudgill and R. Widdus), 1097–9
Enthalpy–Entropy Relationship On the (Dr. R. McGregor and Dr. B. Miličević), 523–5
Entrance Requirements to Universities: Foot in the Door, 1010
Enzymatic Activity of L-Glutamic Dehydrogenase in Liver Mitochondria of Adult and Foetal Rats (P. Koppe and E. Goetze), 887
Enzymatic Degradation of L-Cystine by Cytoplasmic Particles from Cabbage Leaves (M. Tishel and Dr. M. Mazelis), 745
Enzymatic Etching of Single Crystals of Naphthalene (Dr. J. M. Thomas, J. O. Williams, Prof. W. C. Evans and E. Griffiths), 181
Enzyme: Comparison of the Effect of Alpha- and Gamma-radiation on an (Dr. P. M. Kopp et *al.*), 959
Enzyme based on Disulphide Exchange: New Assay of the Ribonuclease-reactivating (P. Venetianer), 643
Enzyme Histochemistry of Developing Human Muscle (Dr. V. Dubowitz), 884
Enzymes: Chondromucoprotein-degrading (Dr. A. J. Barrett), 1188
Enzymes in Electrophoretic Fractions: Human Serum (V. B. Kambli and R. W. P. Master), 532
Enzymes by *Phytophthora infestans*: Production of Pectic (Dr. D. D. Clarke), 649
Eocene, of the Simla Hills of India: Glauconite in the Subathu Beds, (A. D. Kharkwal), 615
Eosinophil Granule revealed by Cytochemical Methods: Morphological Variations in the (Dr. A. J. L. Macario), 873
Eperythrozoon coccoides in Plasma and Spleen of Infected Mice: Distinctive Behaviour of (Dr. P. G. Stansly and C. F. Neilson), 1203
Ephemeral Earth Satellite: Evidence of an (J. P. Bagby), 285
Epidermal Keratin and Epidermal Prekeratin (Dr. R. C. Crounse), 1301

Epithelial Inoculation: Herpes Simplex Virus Particles in the Nerves of Rabbit Corneas after (Dr. C. R. Dawson et *al.*), 316
Epithelium-Choroid Complex of the Eye of the Toad: An Earlier Phase of the Light-evoked Electrical Response from the Pigment (Dr. K. T. Brown and Dr. P. W. Gage), 155–8
Epithelium: Form and Function of Lysosomes in Oral (Dr. J. P. Waterhouse and C. A. Squier), 420
Epstein, Prof. B., and Lomnitz, Prof. C.: Model for the Occurrence of Large Earthquakes, 954–6
Epstein, E.: Identification of l-(o-Carboxyphenylamino)-l-deoxyribulose and Anthranilic Acid in Cultures of the Basidiomycete *Schizophyllum commune*, 855
Epstein, L. M., and Sun, Dr. K. H.: Chemical Reactions induced in Gases by means of a Laser, 1173
Equations of the First Order: Calculus of Variations and Partial Differential (C. Carathéodory), Part I, *review* by Prof. A. Erdélyi, 914
Erdélyi, Prof. A.: Calculus of Variations and Partial Differential Equations of the First Order, *review*, 914
Erdman, Dr. Howard E.: Effects of X-rays on Metamorphosis and Adult Life Span of Flour Beetles, 1427
Erdtman, Prof. G.: Pollen and Spore Morphology/Plant Taxonomy—Gymnospermae, Bryophyta (Text), Introduction to Palynology, III, *review* by Dr. W. G. Chaloner, 16
Erebus, Antarctica: Soils and Micro-organisms from Mount (F. C. Ugolini and Prof R. L. Starkey), 440
Ernst, H., Traelnes, K. R., Altman, Dr. K. I., and Hempelmann, Dr. L. H.: Effect of Thorazine (Chlorpromazine) on Collagen Metabolism, 880
Ernsting, Wing-Cmdr. J.: The Physiology of Human Survival, *review*, 799
Errors: Origin of the Theory of (O. B. Sheynin), 1003
Eruption of an Alaskan Volcano: Evidence of Two Sound Channels in the Polar Atmosphere from Infrasonic Observations of the (C. R. Wilson et *al.*), 163–5
Erythrocyte and Leucocyte Glucose-6-phosphate Dehydrogenase in Italians from Various Ethnic Groups: Electrophoretic Heterogeneity of (A. Bonsignore et *al.*), 876
Erythrocyte Membranes: Isolation of a Glucose-binding Component from Human (Dr. H. Bobinski and Dr. W. D. Stein), 1366–8
Erythrocyte Stroma: Sulphydryl Reagents and Rh Activity of (F. A. Green), 852
Erythrocytes: Facilitated Diffusion in Mouse and Rat (B. Ospina and Prof. F. R. Hunter), 851
Erythropoietic and Granulopoietic Cells in Human Beings: DNA Synthesis Time of (P. Stryckmans et *al.*), 717–20
Erythropoietin and Renin after Experimental Kidney Infarction: Renal Production of (Dr. P. H. Abbrecht et *al.*), 1318
Escherichia coli: Flagella-assisted Cell Fission in (Dr. L. B. Quesnel), 659
Escherichia coli produced by Growth in High Concentrations of Various Salts: Fragile Cultures of (Dr. G. Mangiarotti and Dr. D. Schlessinger), 761–3
Esnouf, Dr M. P., and Jobin, F.: Coagulant Activity of Tiger Snake (*Notechis scutatus scutatus*) Venom, 873–5
Esterase Activity in the Arachnida (P. M. Pollak), 546
Esters by Different Treatments: Modification of Relative Mutagenic Efficiency in Barley of Mesyloxy (A. T. Natarajan and M. S. Ramanna), 1099
Esters by Gas-Liquid Chromatography. Isotope Fractionation of Methyl (Dr. D. S. Sgoutas), 296
Etching of Single Crystals of Naphthalene: Enzymatic (Dr. J. M. Thomas et *al.*), 181
Ethionine: Experimental Porphyria Induced in Rats by (A. Palma-Carlos et *al.*), 977
Ethionine on Liver Affinity for Iron: Early Effect of (Dr. T. D. Kinney, N. Kaufman and Dr J. V. Klavins, 856
Ethnic Groups: Electrophoretic Heterogeneity of Erythrocyte and Leucocyte Glucose-6-phosphate Dehydrogenase in Italians from Various (A. Bonsignore et *al.*), 876
Ethyl Halides: Relation between Thermodynamic Property Change and Vibrational Frequency Shift in (Dr. J. Lielmezs), 742
Ethylene Injury to Carnations by Low Concentrations of Carbon Dioxide: Prevention of (W. H. Smith and J. C. Parker), 100
Ethylene in the Presence and Absence of Carbon Dioxide: Exposure of Cut Flowers to (W. H. Smith et *al.*), 99
Ethylene by Self-indicating Soda-lime: Absorption of (R. Nichols and A. Topping), 217
N-Ethylmaleimide: Sulphur Metabolism: the Usefulness of (Dr. R. J. Ellis), 1266–8
Ettre, L. S.: Open Tubular Columns in Gas Chromatography, *review* by E. A. Walker, 1022

5-Hydroxytryptamine in the Rat Brain· Fate of Intracisternally Injected (Dr. M. Bulat and Prof. Z. Supek), 637
5-Hydroxytryptophan Uptake by Dog Thyroid 'C' Cells, and its Possible Significance in Polypeptide Hormone Production (Prof. A. G. E. Pearse), 598–600
N-Hydroxyurethane: Antitumour Activity of (Miss M. A. Hahn et *al*), 984
Hykes, P., and Jirsa, Dr. M.: Preparation, Properties and Metabolism of Iodinated Bromosulphthalein, 645
Hyman, Dr. Edward S.· Transfer of Metabolic Energy to Sodium, 836
Hymenopenaeus tropicalis and *Parapenaeus americanus* from Brazil. New Records of the Shrimps (M. N. Mistakidis and G. de S. Neiva), 434
Hyperaesthesia. Central Mechanism of (L. N. Smolin and N. N. Samko), 1412
Hyperin and Nonacosane Constituents of Tutsan (K. R. Hargreaves), 417
Hyperploidy Effect of Lymphocyte Extract on Fibroblasts *in vitro* (Dr. P. J. Fialkow and Prof. S. M. Gartler), 713–5
Hypersensitivity induced in Albino Mice by Melanocyte-stimulating Hormone (Dr. A. Sakamoto), 1370
Hypersensitivity Reactions. Origin and Specificity of Mononuclear Cells in Delayed (Dr. T. U. Kosunen), 1418
Hypocholesteraemic Activity: New Class of Orally Effective Antifertility Agents with (Dr. Horace A. DeWald et *al.*), 538
Hypoglycaemic Activity of an Anhydroformaldehyde Aniline–Insulin Mixture: Oral (Dr. J. K. Wales et *al.*), 88
Hypophyseal Portal Blood: Thyrotrophin Releasing Factor in (Dr. R. L. W. Averill et *al.*), 144
Hypothalamic Extracts: Increase in Plasma Growth Hormone Level in the Monkey following the Administration of Sheep (Dr. J. F. Garcia and Prof. I. I. Geschwind), 372–4
Hypothesis—testing in Classification (Dr. D. W. Goodall), 329
Hysteresis Loops from Both Surfaces of a Magnetic Film: Simultaneous Magneto-optic Recording of (Dr. R. Carey et *al.*), 730

IANCONESCU, M., and Peleg, Dr. B. A.: Spermagglutination and Sperm-adsorption due to Myxoviruses, 1211
Ice-forming Nuclei in the Atmosphere (J. B. Stewart, I. Ross and C. M. Stevenson), 1164
Ice Nucleation Potential of Meteoritic Material: Further Tests on the (Prof. M M. Qureshi and J. Maybank), 508
Ice Nucleation by Proteins and Surface Films (L. F. Evans), 281
Ice Tubes· Growth of (A. T. J. Hayward), 172
Ice Wedges in Hampshire: Fossil (J. Lewin), 728
Ijlst, L., and Verschure, R. H.: Apparatus for Continuous Dielectric-medium Separation of Mineral Grains, 619
Ikeya-Seki Comet· Observations of the Low-energy Photon Fluxes during the Solar Approach of the (P T. Gronstal and R. P. Bukata), 176
Iliashenko, B. N.· Sensitivity of the Phage and Complementary Strands of the Replicative Form of Phage φ X 174 Deoxyribonucleic Acid to Ultra-violet Light, 430
Illex illecebrosus: Feeding Habits of the Squid, (Dr. H. J. Squires), 1321
Illman, Dr. O., and Ghadially, Dr. F N.· Effect of Oestrogen on the Small Pigmented Spots in Hamsters, 1303
Ilmenite: Pseudorutile—a New Mineral Intermediate between Ilmenite and Rutile in the Natural Alteration of (Dr. G. Teufer and A. K. Temple), 179–81
Ilyin, V S., and Titova, G. V.: Hormone–Enzyme Complex: Insulin–Hexokinase, 644
Immune Response *in vitro*: RNA Synthesis in Macrophages in Relation to the Secondary (Dr. G. Harris), 154
Immunity in Chickens grafted *in ovo* with Allogenic Thymus: Suppression of Homograft (Prof. B. D Janković and K. Isaković), 93
Immunity against Fall-out: No, 111
Immunization for the Antirabies One-day-egg Vaccine: Simplified Course of (Prof. K. Yoshino, Prof. Y. Yamamoto and K. Arai), 542–4
Immunochemical Reactions of Conalbumin and its Metal Complexes (C. Tengerdy, Dr. P. Azari and R. P Tengerdy), 203
Immunofluorescent Staining of Globule Leucocytes in the Colon of the Sheep (C. Dobson), 875
Immunoglobulins: Biosynthesis of, Free Light Chain as an Intermediate in the Assembly of γG-molecules (Dr. B. A. Askonas and Dr. A R. Williamson), 369–72
Immunoglobulins in Human Spleen· Cells producing Ig D (B. Pernis, et *al.*), 424
Immunological Determination of Human Follicle Stimulating Hormone (A Wolf), 942
Immunological Tolerance of the Female to Homologous Seminal Plasma Protein (J. O Menzoian and Dr. M. M. Ketchel), 133–5
Immunological Unresponsiveness in Adult Rats to the Nematode *Nippostrongylus brazilensis* induced by Infection in Early Life (E. E. E. Jarrett, Prof. W. F. H. Jarrett and Dr. G. M. Urquhart), 1310
Impact Phenomena on Metal Surfaces: Atomic and Ionic (Dr. M Kaminsky), *review* by Dr. J. Adam, 347
Impact with Special Reference to the Lunar Surface· Luminescence caused by Proton (J. Schutten and Th. Van Dijk), 470 (J. E. Geake and G. Walker), 471
Impulse Trigger Sites in Hippocampal Neurones: Activation of "Secondary" (Dr. D. P. Purpura), 1317
Impurities on Ionization Times in Shock-heated Argon: Effect of Hydrogen-containing (Dr. P. B. Coates), 300
Inclusion in South African Diamonds: Pyrrhotite: a Common (W. E. Sharp), 402
Incubation in Agar: Discriminating Power of Rodent DNA on (Dr. A. McLaren and Dr. P. M. B. Walker), 486–90
Independence for Universities, I, Plain Words by Sir Ifor Evans, 2
Index, Science Citation: Drop More Names, 556
Index of Soil Nitrogen Availability: Chemical (Dr. D. R. Keeney and Prof. J. M. Bremner), 892
Indexes for Time-course Curves: Rapid Method for determining Numerical (J. L. Lyon and R. J. Coffelt), 330
India: Devonian Fishes from Kashmir, (V. J. Gupta and Dr. R. H. Denison), 177
Glauconite in the Sabathu Beds (Eocene) of the Simla Hills of (A. D Kharkwal), 615
Indiana University: Appointment, 674
Indolyl-3-acetic Acid in Intact Cucumber Plants: Distribution of Labelled (Dr J.-M Bollag and Dr. E. Galun), 647
Industrial Archaeology (K. Hudson), *review* by Prof. Asa Briggs, 565
Industrial Training, 671
Industrialized Building, 1332
Industrialized Societies: Forty Million Englishmen? 1007
Infectious Drug Resistance *In vivo* Transfer of (J. R. Walton), 312
Influenza *A/equi*-2 in Switzerland· Outbreak of (M. F Baccaud, M. Couard, F. Burki, H. Gerber and Col. J. Lohrer), 101
Influenza Virus: Nucleic Acid of (P. Davies and Dr. R. D Barry), 384–7
Information: BA Supplement—Nottingham 1966, 1052
Presentation of Technical, Better Writing, 557
Information and Communication Theory (A. M. Posie), *review* by Prof. J. T. Allanson, 570
Information Exchange, 902, 904, Groups (IEG), Preprints Galore, 897
Infra-red Determination of the Percentage of Crystallinity in Apatitic Calcium Phosphates (J. D. Termine and Dr. A. S. Posner), 268–70
Infra-red Luminescence (Fluorescence) and Reflectance of Coals, Coal Derivatives and Graphite (Dr. R. A. Friedel and H. L. Gibson), 404
Infra-red Spectra of Gaseous Hydrogen-bonded Complexes: Band-broadening in (L. Al-Adhami and Prof. D. J. Millen), 1291
Infra-red Spectroscopic Investigations of a New Acid Mucopolysaccharide isolated from Human Gastric Juice (T. Terho, K. Hartiala and I. Hakkinen), 198
Infra-red Spectroscopy at High Pressures: Far (Dr. C. C. Bradley, Dr. H. A. Gebbie, A. C. Gilby, V. V. Kechin and J. H. King), 839
Infra-red Spectroscopy: Identification of Methyl Octanoate Derivatives from Autoxidized Methyl Linoleate by Mass Spectrometry, Nuclear Magnetic Resonance and (R. J. Horvat et *al.*), 298
Infra-red Spectroscopy: Laboratory Methods in (edited by R. G. J. Miller), *review* by R. J. Mesley, 348
Infra-red Spectroscopy of Tissues in the 700–400 cm^{-1} Region (Prof. L. May), 412
Infra-red Stars (Dr. V. C. Reddish), 395
Infra-red Studies of Hydrogen Bonding in Gaseous Mixtures· Far (Dr. G. L. Carlson, R. E. Witkowski and Dr. W. G. Fateley), 1289–91
Infrasonic Observations of the Eruption of an Alaskan Volcano· Evidence of Two Sound Channels in the Polar Atmosphere from (C. R. Wilson et *al.*), 168–5
Ingels, jun., Neil P., and Thompson, Dr. N. P.: Electrokinematic Theory of Muscle Contraction, 1032–5
Inhaled Particles in Human Lungs Deposition of (C. N. Davies and D. C Muir), 90
Inhibition in the Lateral Geniculate Nucleus of the Rat: Mechanism of Recurrent (Dr. A. J. Sefton and Dr W. Burke), 1276–8
Inhibitor-induced Changes in the Optical Rotatory Dispersion of Aspartate Transcarbamylase: Substrate- and (E. A. Dratz and Prof. M. Calvin), 497–501
Inhibitory Effect of *Lactobacillus acidophilus* (Dr J. Tramer), 204
Inhibitory Transmitter? Is γ-Aminobutyric Acid an (Prof K. Krnjević and Dr. S. Schwartz), 1372–4
Innervation of the Temporo-mandibular Joint: Reflex (B E Greenfield and Dr. B. Wyke), 940
Inorganic Chemistry in Non-Aqueous Solvents (A. K. Holliday and A G. Massey), *review* by Dr. S. R. C. Hughes, 1237
Inorganic Close-packed Structures· Space-group Representation in Condensed Models of (Dr. J. Lima-de-Faria), 281
Inorganic Compounds: Thermochemical Data Storage for (Dr. R. A. J. Shelton and Dr. S. Blairs), 1397
Inputs on Deiters Neurones: Convergence of (Dr. V. J. Wilson, Dr. M. Kato and B. W. Peterson), 1409–11
Inputs: Evaluation of the Queue Length Distribution for some Queues with Correlated (Dr. T. Lewis), 1106
Inscoe, Dr May N.: Losses due to Adsorption during Filtration of Aqueous Solutions of Polycyclic Aromatic Hydrocarbons, 1083–5
Insect Blood Volume: Micro-determination of (Dr. H. H. Shatoury), 317
Insect (*Carausius morosus*): Neural Fat-body Sheath in a Phytophagous (Dr. S. H. P. Maddrell and Dr. J. E. Treherne), 215
Insect Cells as revealed by Electron Microscopy: Intranucleolar DNA Components in (Dr. J. Jacob), 36–8
Insecticide Residues in Soil Invertebrates: Organochlorine (Dr. B N. K. Davis and R B. Harrison), 1424
Insects of Ghana: Agricultural (compiled by J. Forsyth), *review* by R. F Avery, 463
Insects: Relation of Temperature to the Duration of the Development of (M. D. Mountford), 993
Insects in Southern Africa (Dr. B. Smit), *review* by Sir Vincent Wigglesworth, 1127
Insemination with Spermatozoa separated by Sedimentation: Attempt to predetermine the Sex of Calves by Artificial (Dr. B. C Bhattacharya et *al*), 863
Institute for Advanced Studies of Design· Parliament in Britain, 790
Institute of Physics and the Physical Society· Officers, 225, Successful Year, 223, Presidential Address by Sir Gordon Sutherland. How to Spend Money? 792
Institute of Technology Bradford· Appointment, 451
Institute of Technology: Massachusetts, Appointments, 114, Growth of, 225
Insulin by Guinea-pig Taenia Coli. Response to (S. H. Grossman and Dr. K. L. Manchester), 1300
Insulin–Hexokinase: Hormone–Enzyme Complex· (V. S. Ilyin and G. V. Titova), 644
Insulin labelled with Iodine-131. Purification of (Å. Hoye), 746
Insulin on Purified Creatine Phosphokinase: Effect of (Dr. R. B. Conn, jun), 195
Integral Transforms and Operational Calculus (V. A. Ditkin and A P. Prudnikov), *review* by Dr. M A. Jaswon, 235
Intensity Dependent Refractive Indices: Variable Focal Length Lenses using Materials with (P. D. McWane), 1081
Interaction of Bubbles and Bacteria in the Formation of Organic Aggregates in Sea-water (R. T. Barber), 257
Interaction of Elementary Particles: Weak (Prof. L. B. Okun'), *review* by Dr. P. T. Matthews, 801
Intercontinental Conodont Correlation of the Palaeozoic Sediments of the Bonaparte Gulf Basin, North-western Australia (P. J Jones and E. C. Druce), 357–9
Interferenzmikroskopie: Methoden und Ergebnisse der Zytophotometrie und (edited by W. Sandritter and G. Kiefer), Symposium, *review* by Dr. J. Kruszynski, 1345

Interferons: Heterogeneity of Rabbit Serum (Dr. Y. H. Ke *et al.*), 541
Intergranular Voids and Cracks in an Irradiated Austenitic Steel tensile-tested in the Temperature Range 650°–850° C. Formation of (Dr. R. Sumerling), 512–4
International Atomic Energy Agency: Vienna Safeguards, 555
International Nutrition Meeting at Hamburg (Dr. M. Pyke), 914
Interneurones in the Lumbar Spinal Cord. Effect of Muscle Loading on the Behaviour of (S. M. Hill *et al.*), 425
Interstellar Vehicle propelled by Terrestrial Laser Beam (Prof. G. Marx), 22
Interstitial Dislocation Loops in Beryllium Oxide irradiated at High Temperatures (R. C Rau), 71
Interstratified Mineral from Micas: Synthesis of an (S. Ueda and Prof. T. Sudo), 1393
Intervertebral Disks. Isolation of a Chondroitin Sulphate Protein Complex from Bovine (Dr. D. A. Lowther and E. Baxter), 595–7
Intestine of the Chick Embryo by Actinomycin *D*: Elevation of Alkaline Phosphatase Activity in the (Dr. R. D. Grey and Prof. F. Moog), 418
Intracellular Repressor of Alkaline Phosphatase (Dr. S. W. Bowne, jun., Dr. J. A. Ondrey and Dr. J. L. Wise), 980
Intracisternally Injected 5-Hydroxytryptamine in the Rat Brain: Fate of (Dr. M. Bulat and Prof. Z. Supek), 637
Intragenic Recombination Polarity in (Dr. H L. K. Whitehouse), 709
Intranucleolar Deoxyribonucleic Acid Components in Insect Cells as revealed by Electron Microscopy (Dr. J. Jacob), 36–8
Intraventricular Administration of Nalorphine to Mice Implanted with Pellets of Morphine (C. Maggiolo and F. Huidobro), 540
Intrusions. Temperature Conditions of Salt Dome (P. E. Kent), 1387
Inverse Compton Effect in Quasars (M. J. Rees and Dr. D. W. Sciama), 805–7
Inversion of the Sachse Hexagon: Transition State in the (J. A. Christiansen), 184
Invertebrates Organochlorine Insecticide Residues in Soil (Dr. B. N. K. Davis and R. B. Harrison), 1424
Iodate: Anomalous Protein Binding of Iodine-131 in the Presence of (W. T. Baker and G. Owen), 641
Iodinated Bromosulphthalein: Preparation, Properties and Metabolism of (Dr. M. Jirsa and P. Hykeš), 645
Iodine in the Continuum of the $B^3\Pi_{0u}^+$—$X^1\Sigma_g^+$ System, and by Collisional Release inside the Banded Region: Reaction with Propane of I($5^2P_{1/2}$), produced by Photolysis of (Dr. A B Callear and J. F Wilson), 517
Iodine-131-labelled Atabrine by Ehrlich Ascites Tumour and by Sarcoma *S*-180 *BALB*. Uptake of (Dr. L. J. Anghileri), 878
Iodine-131-labelled Iodo-amino-acids in the Plasma Protein-bound Iodine Assay: Recoveries of (Dr. M. W O'Halloran and M. L. Wellby), 1195–7
Iodine-131 in the Presence of Iodate Anomalous Protein Binding of (W. T. Baker and G. Owen), 641
Iodine-131. Purification of Insulin labelled with (Å. Hoye), 746
Iodo-amino-acids in the Plasma Protein-bound Iodine Assay·Recoveries of Iodine-131-labelled (Dr. M. W. O'Halloran and M. L. Wellby), 1195–7
Ioneda, T., *et al.*: Purification and Chemical Constitution of the Phospholipids from *Corynebacterium diphtheriae* P.W.8, 81
Ion Exchange Method of estimating Strontium-90 and Other Radionuclides in Rainwater (C. Brenan, J. H. Lovatt and H. Smith), 68
Ion-exchange Polymers: Interpretation of Electrolyte Invasion Data for (C. J. Attridge), 1293
Ionic Complexes of Thiourea (Dr. J. C. A. Boeyens and Prof. F. H. Herbstein), 588–90
Ionic Impact Phenomena on Metal Surfaces: Atomic and (Dr. M. Kaminsky), *review* by Dr. J. Adam, 347
Ionization Detector for Gas-phase Titration (T. L. Foldvari, J. E. A. Toni and Dr. K. S. Lion), 294–6
Ionization Detector with Helium and Neon as the Carrier Gases: Sensitivity to Oxygen of an (P. J. Bourke and R. W. Dawson), 409
Ionization Times in Shock-heated Argon: Effect of Hydrogen-containing Impurities on (Dr. P. B. Coates), 300
Ionized Atmosphere: Interactions of Space Vehicles with an (edited by S. F. Singer), *review* by Dr. A. P. Willmore, 798
Ionizing Radiation in Aromatic Materials: Diffusion of Triplet Excitons produced by (Dr. R. Voltz *et al.*), 405
Ions, Doubly-charged Negative, of Oxygen, Fluorine, Chlorine and Bromine (Dr. W. K. Stuckey and Prof. R. W. Kiser), 963
Ions in a Model System driven by Water Flow: Transport of Alkali (J. Rastas *et al.*), 1152–4
Iris of Rabbits Extrusion of ATPase Activity from Pinocytotic Vesicles of Abutting Endothelium and Smooth Muscle to the Internal Elastic Membrane of the Major Arterial Circle of the (Dr. C. A. Santos-Buch), 600–2
Iron (III) Complex with Spin, $S=3/2$: Molecular and Crystal Structure of a 5-Covalent (B F. Hoskins *et al.*), 627
Iron· Early Effect of Ethionine on Liver Affinity for (Dr. T. D. Kinney), 856
Iron Enneacarbonyl (M. H. Chisholm, Dr. A. G. Massey and Dr. N. R. Thompson), 67
Iron in Ferredoxin and Rubredoxin: Nature of the Non-haem (G. Palmer and H. Brintzinger), 189
Iron-55 in Marine Environment and in People who eat Ocean Fish (H. E. Palmer, T. M Beasley and Dr. T. R. Folsom), 1253
Iron-bearing Nepheloid Layer near Key West, Florida (D. F. Wilson and E. J. Zillioux), 506
Iron Silicate Deerite: Low Spin Ferrous Iron in the (I. S. E. Carmichael *et al.*), 1389
Ironstone Series: Depositional Environment of the Cleveland (T. M. Chowns), 1286
Irradiated Austenitic Steel tensile-tested in the Temperature Range 650°–850° C: Formation of Intergranular Voids and Cracks in an (Dr. R. Sumerling), 512–4
Irradiated Foods: Toxic Effects of (G. Löfroth), 302
Irradiated Mice to Infection with *Mycobacterium lepraе*: Enhanced Susceptibility of Thymectomized and (Dr. R. J. W. Rees), 657
Irradiated Mice· Recovery Effect of Heterologous DNA from Various Organs on (Dr. N. Savković *et al.*), 1179
Irradiated Orthorhombic Ammonium Perchlorate: Thermal Decomposition of (Dr. P. J. Herley and Dr. P. W. Levy), 1287
Irradiated Rat Thymocytes by Post-irradiation Oxygen Deprivation: Prevention of Nuclear Damage in (Dr. J. F. Whitfield and Dr. H. Brohee), 775
Irradiated Rat Thymocytes: Roles of Phosphate and Respiration in Nuclear Damage in (J. F. Whitfield and T. Youdale), 212
Irradiated Rhodopsin Solution: Optical Rotation of (Y. Kito and M. Takezaki), 197
Irradiated Sucrose on the Chromosomes of Human Lymphocytes *in vitro*: Effects of (Dr. M. W. Shaw and E. Hayes), 1254–6
Irradiation on Skin Collagen: Effect of Ultra-violet (E. Bottoms *et al.*), 97
Irradiation on Synthesis of Deoxyribonucleic Acid: Effect of Total Dose, Dose Rate and Time of (L. O. Chang, S. S. Williams and Dr. W. B. Looney), 300–2
Isaac, Dr. E. D., *et al*· Simultaneous Magneto-optic Recording of Hysteresis Loops from Both Surfaces of a Magnetic Film, 730

Nitrogen Balance Experiments: Some Theoretical Considerations (Dr. L. R. Njaa), 1413
Nitrogen Dioxide with Polymethyl Methacrylate: Electron Spin Resonance Studies of the Reactions of Nitric Oxide and (J. Law), 1351–4
Nitrogen Isotopes in Dutch Coals and Natural Gas: Determination of the Abundance of Carbon and (C. Bokhoven and H. J. Theeuwen), 927–9
Nitrogen Source by *Prototheca zopfii*: Utilization of Adenine but not Nitrate as (J. L. Stacey and Dr. F. J. Casselton), 862
Nitrogen by Strong Acids: Hydrolysis of Soil (Dr. J. G. Quinn and Dr. M. Salomon), 664
Nitrogenous Fertilizer on the Yield and Dry Matter Content of Marrow Stem Kale at Various Sowing Dates Influence of the Level of (R. D. Toosey and J. W. Usher), 216
S-Nitroso Derivatives of Hexane-1-thiol and Hexane-1,6-dithiol: Photochemistry of the (Dr J. Barrett *et al.*), 848
Nitsch, J. P., and Dennis, Jun., F. G.. Identification of Gibberellins A_4 and A_7 in Immature Apple Seeds, 781
Njaa, Dr. L. R.: Nitrogen Balance Experiments: Some Theoretical Considerations, 1413
Noble, John: Mirror-images and the Forebrain Commissures of the Monkey, 1263–6
Noble Gases: Vibrational Relaxation of Carbon Dioxide in Mixtures with (B. J. Lavercombe), 63
Noctilucent Clouds observed in Antarctica (R. J. Francis, J. M. Bennett and D. L. Seedsman), 398
Nocturnal Migrants: Grouping of (E. Eastwood and G. C. Rider), 1143–6
Nodosa-like Disease in Outbred Mice: Polyarteritis (R. D. Wigley and K. G. Couchman), 319
Noise· Aircraft, Parliament in Britain, 558
Obstacle Detection using Ambient or Self-generated (Dr. J. P. Wilson), 218
Nomenclature of Elements (Dr. R. Shuttleworth), 1178
Nomenclature for the Fibrous Calcium Silicates, and a Study of Xonotlite Polytypes: System of (Dr. J. A. Gard), 1078
Nomenclature of the Keuper–Lias Facies of the Bristol Channel Region (E. C. Willey), 398
Nomenclature of Metallic Elements (Dr. A. Wolfenden), 632
Nonacosane Constituents of Tutsan: Hyperin and (K. R. Hargreaves), 417
Non-elastic Mantle: Meeting at Newcastle upon Tyne, (Dr. D. C. Tozer), 239
Non-linear Acoustics· Meeting at Birmingham (Dr. B. K. Gazey), 803
Non-Newtonian Flow: Some Engineering Aspects of (Dr. J. Harris), 579–81

Notechis scutatus scutatus, Venom: Coagulant Activity of Tiger Snake, (F. Jobin and Dr. M. P. Esnouf), 873–5
Nottingham, 1966 British Association Supplement, 1051–66
Nottingham—a Century Ago: BA in, 1056–8
Nottingham between the Wars: BA Meeting in 1937, 1059, H G. Wells on Education, 1061–3
Nottingham: University of, Appointment, 225
Noye, B. J., and Radok, J. R. M. Southern Storm Centres and Ocean Wave Spectra, 287
Noyes, H. Pierre, *et al.* (edited by): Annual Review of Nuclear Science, Vol. 15, *review* by J E. Terry, 569
NRDC (Britain's National Research and Development Corporation): Public Exploitation, 899
Nuclear Damage in Irradiated Rat Thymocytes by Post-irradiation Oxygen Deprivation: Prevention of (Dr. J. F. Whitfield and Dr. H. Brohee), 775
Nuclear Damage in Irradiated Rat Thymocytes: Roles of Phosphate and Respiration in (J. F. Whitfield and T Youdale), 212
Nuclear DNA from Rat Liver Cells: Comparison of Physicochemical Properties of Mitochondrial and (T. B Kazakova and K. A Markosian), 79
Nuclear Division. Culture Method of growing *Entamoeba histolytica* and Other Anaerobic Amoebae for the Study of their (J. P Dubey and S. R Das), 992
Nuclear Energy Agency (European): More Power for *Dragon*, 788
Nuclear Fission: Liquid Drop Model and Asymmetric (Dr. S. P. Morris and Dr. R. C. Sharma), 624
Nuclear Fuel for Space, 1223
Nuclear Magnetic Relaxation Investigations of Water: Proton (Prof. R. E. Glick and K. C. Tewari), 739
Nuclear Magnetic Resonance and Infra-red Spectroscopy Identification of Methyl Octanoate Derivatives from Autoxidized Methyl Linoleate by Mass Spectrometry, (R. J. Horvat *et al.*), 298
Nuclear Magnetic Resonance Spectroscopic Studies of the Interaction of Phospholipids with Cholesterol (D. Chapman and S A Penkett), 1304
Nuclear Magnetic Resonance Spectrum Changes accompanying Rigor Mortis (Prof. M. V. Sussman and L. Chin), 414
Nuclear Physics and Nuclear Chemistry: Dictionary of (edited by H. Rau), Second Edition, *review* by Dr. J. B. Sykes, 462
Nuclear Reactions High Energy (Dr. A. B Clegg), *review* by C J. Batty, 16
Nuclear Reactor Operation in Space (Prof. J. Sayers and Prof. J. Walker), 60
Nuclear Science, Vol. 15: Annual Review of (edited by E. Segrè, G. Friedlander and H. P. Noyes), *review* by J. E Terry, 569
Nuclear Variation between Diploid Angiosperms (Dr. H. Rees, F. M. Cameron, M. H. Hazarika and G. H. Jones), 828–30
Nuclear Weapons Tests: Radioactive Fallout from (edited by A. W. Klement, jun.), *review* by D. H. Peirson, 682
Nucleation by Elastin (Dr A. E. Sobel, S Leibowitz, Dr. R. G. Eilberg and Dr. F. Lamy), 45–7
Nucleation in Polymer Crystallization: Orientation-induced (Dr. F. L. Binsbergen), 516
Nucleation by Proteins and Surface Films: Ice (L. F. Evans), 281
Nucleation of the Solid Phase by Cavitation in an Undercooled Liquid which expands on Freezing (J. D Hunt and K. A. Jackson), 1080
Nuclei in the Atmosphere. Ice-forming (J. B Stewart *et al.*), 1164
Nuclei of Galaxies Production of Mesons in the (Dr. D. F. Falla), 165–8
Nuclei: Patterns of Spontaneous Rhythmic Activity within Various Thalamic (Dr. P. Andersen *et al.*), 888
Nuclei of Two Mouse Tumours: DNA Content of Mitotic (Dr. E L. Alpen and M. E. Johnston), 715–7
Nucleic Acid Bases: Electron Spin Resonance Examination of Charge Transfer Complexes of Polycyclic Carcinogens and (Dr. J B. Jones *et al.*), 309
Nucleic Acid of Influenza Virus (P. Davies and Dr. R. D. Barry), 384–7
Nucleic Acid Synthetic Patterns in Synchronized Mammalian Cells (Dr. F. H. Kasten and F. F. Strasser), 135–40
Nucleic Acids. Effect of Urethan on (S. V. Bhide and K. J. Ranadive), 82
Use of Neutron Activation in the Characterization of Small Quantities of (Dr. K. Murray and R. E. Offord), 376–8
Nucleotide-dependent Diaphorase in Foetal, Newborn and Adult Cattle: Reduced Diphosphopyridine (Dr. J. E. Smith and Dr. E. Beutler), 756
Nucleus: The Cell, Meeting at Rijswijk, the Netherlands (Prof. H. Busch), 1347
Nugent, L. J.: Laser Radar Probe for the Measurement of Metastable Nitric Oxide in the Upper Atmosphere, 1349–51

Oxidase Activity in Ecotypic Populations of *Typha latifolia* L. (S. J McNaughton), 1377–9
Oxidation and Combustion Reviews, Vol. I (edited by C. F. H. Tipper), *review* by Dr. A. Fish, 913
Oxidation of Dilute Nickel–Chromium Alloys Mechanism of (Dr. G. C. Wood and T. Hodgkiess), 1358–61
Oxidation of Sulphur Dioxide in Air at 950° C: Co-operative Influence of Carbon Monoxide and Nitric Oxide (J T. Shaw and P. D Green), 1171
Oxidation of Titanomagnetites and Self-reversal (W. O'Reilly and S. K. Banerjee), 26–8
Oxidation of Transition Metals in Molten Lithium Chloride–Potassium Chloride Eutectic by Mercuric Chloride (M. Henderson, Prof. J Lewis, Dr. D. J. Machin and Dr. A. Thompson), 966
Oxidative Metabolism to Particle Entry and Destruction in Phagocytosing Cells Relationship of Glycolytic and (R. J. Selvaraj and Dr. A. J. Sbarra), 1272–6
Oxidative Phosphorylation by D-threo- and L-threo-Chloramphenicol. Impairment of (Prof. J. B. Hanson and W. A. Krueger), 1322
Oxides of Niobium, Tungsten, Molybdenum and Titanium: Crystallographic Shear and Diffusion Paths in Certain Higher (Dr. S. Andersson and Dr. A. D. Wadsley), 581–3
Oxides: Structure Studies or Ternary Vanadium–Molybdenum (Dr. H. A. Eick and L. Kihlborg), 515
Oxindoles on the Growth of Tobacco Tissue Cultures Effect of (Dr. J S Weis), 1216
Oxygen Deprivation: Prevention of Nuclear Damage in Irradiated Rat Thymocytes by Post-irradiation (Dr. J F. Whitfield and Dr. H. Brohee), 775
Oxygen: Doubly-charged Negative Ions of (Dr. W. K. Stuckey and Prof R. W. Kiser), 963
Oxygen Dissociation of Sheep Haemoglobins A and B in Solution (Dr. J. A. Sirs), 533
Oxygen Electrode: Reversible (J. P. Hoare), 703–5
Oxygen-inhibited Grain Growth in Thin Films of Semi-conducting Cuprous Iodide (C. S. Herrick , 958
Oxygen of an Ionization Detector with Helium and Neon as the Carrier Gases. Sensitivity to (P. J. Bourke and R. W. Dawson), 409
Oxygen Isotopic Composition of Phosphate from Shells of some Living Crustaceans (A. Longinelli and M. Sordi), 727
Oxygen-18 : Oxygen-16, Ratios of, in Phosphate and Carbonate from Living and Fossil Marine Organisms (Dr. A Longinelli), 923–7
Oxygen Reduction on Titanium Nitride in Alkaline Electrolyte (Dr. J. Giner and L. Swette), 1291
Oxygen (Symposium sponsored by New York Heart Association), *review* by Dr. I. S. Longmuir, 800
Oxygen Uptake and Glycolic Acid Oxidase in *Typha latifolia* L. Leaf Disks: Light-stimulated (S. J. McNaughton), 1197
Oxyhaemoglobin from Cord Blood: Large-scale Crystallization of Purified Human Foetal (G. Stöffler et *al*), 768
Oxytetracycline Microbiological Transformation of (Dr J. A. Last and Prof. J. F. Snell), 1002

PAMPLITUDES from *Longshot* at Australian Stations (J Cleary), 954
Paccaud, M F , Couard, M., Eurki, F., Gerber, H., and Löhrer, Col. J.: Outbreak of Influenza A/*equi*-2 in Switzerland, 101
Pacific, *Octopus dofleini martini*: Spermatophores and Spermatophoric Reaction in the Giant Octopus of the North (Dr. T. Mann et *al*), 1279–82
Packing Considerations: Direct Solution of Organic Crystal Structures from Molecular (Dr. D Rabinovich and Prof. G M J. Schmidt), 1391–3
Packing of Hard Spheres with Five-fold Symmetry A Dense (J. A R Clarke), 280 (Prof J. D. Bernal), 280
Packing of Spheres Fine Structure in the Radial Distribution Function from a Random (Dr. G. Mason and Dr. W. Clark), 957
Pae, Dr K. D., Morrow, Dr. D. R., and Sauer, Prof. J. A.. Interior Morphology of Bulk Polypropylene, 514
Paes de Carvalho, Prof. A , Hoffman, Prof B. F., and Langan, Dr W. B : Two Components of the Cardiac Action Potential, 938–40
Paghis, I., et *al.* (edited by) Physics of the Earth's Upper Atmosphere, *review* by Dr. P C Clemmow, 459
Paint Technology Manuals, Parts 4 and 5, *review* by Dr. L. Valentine, 1019
Paints: Testing of, *review* by Dr. L. Valentine, 1019
Palaeozoic Atlantic-Island Arcs of Lower (Prof J T. Wilson), 680
Palaeozoic Sediments of the Bonaparte Gulf Basin, North-western Australia. Intercontinental Conodont Correlation of the (P. J. Jones and E. C. Druce), 357–9

Phage and Complementary Strands of the Replicative Form of Phage φX 174 DNA to Ultra-violet Light: Sensitivity of the (B. N. Iliashenko), 430
Phagocytosing Cells. Relationship of Glycolytic and Oxidative Metabolism to Particle Entry and Destruction in (R J. Selvaraj and Dr. A. J. Sbarra), 1272–6
Phalangida. Cuticular Structure in the (C A. Grainge and Dr. R G. Pearson), 866
Pharbitis Embryos: *In vitro* Formation of Adventitious Organs by (Dr. S. Matsubara and Dr. R. Nakahira), 1208–10
Phase Separation in Glass Ceramics: Three-dimensional View of (Dr. A. J. Majumdar et *al.*), 622–4
Phaseoleae: Ecological Significance of Anthocyanins in the Seed Coats of the (Dr W. R. Stanton and B. J. Francis), 970
Phenolic Content of Smoke from Experimental Cigarettes: Reduced Benzo(*a*)-pyrene and (R. J. Shamberger), 86

Phenothiazine Derivatives to the Corresponding Sulphoxides on Thin-layer Plates: Conversion of (J. Kofoed, Dr. C. Korczak-Fabierkiewicz and Prof. G. H. W. Lucas), 147–50
Phenylalanine Deaminase in Extracts of the *Proteus–Providence* Group: Specific Activity of (Dr. J. A. Smit), 1003
Phenylmethylsulphonylfluoride with Reduced Wool as Substrate Trypsin Inhibition by (Dr. P. T. Speakman and R. E. Yarwood), 201
Phenyl-β-D-xylopyranosides (II): Synthesis of Substituted (C. K. de Bruyne and A. Vervoort), 1292
Pheromone of an Australian Termite: Isolation of the Scent-trail (Dr. B. P. Moore), 746
Philosphical Foundations of Physics (R. Carnap, edited by M. Gardner), *review* by R. G Swinburne, 1235
Philosophy: Science, Folklore and (H Girvetz et *al.*), *review* by Dr. R. Harré, 458
Philpot, J. St. L , and Horgan, V. J.: Diminution in Apparent Organic Peroxide ("Pro-blue") in Mice given an Oral Contraceptive, 597
Phormia regina (Meigen): Phosphatidyl Carnitine: a Possible Intermediate in the Biosynthesis of Phosphatidyl β-Methylcholine in (H. M. Mehendale et *al.*), 759–61
Phosphatase Activity in the Intestine of the Chick Embryo by Actinomycin D: Elevation of Alkaline (Dr. R. D. Grey and Prof. F. Moog), 418
Phosphatase Intracellular Repressor of Alkaline (Dr. S. W. Bowne, jun., *et al.*), 980
Phosphatase Isoenzymes: Electrophoretic Separation of Serum Acid (Dr. A. F. Goldberg et *al*), 41–3
Phosphate and Carbonate from Living and Fossil Marine Organisms: Ratios of Oxygen-18: Oxygen-16 in (Dr. A. Longinelli), 923–7
Phosphate into Phospholipids and Phosphoproteins of Nerve Endings of Developing Rat Brain. Acetylcholine and the Incorporation of [^{32}P] (Dr. A. A. Abdel-Latif), 530
Phosphate in the Rat Antagonistic and Synergistic Actions of Thyrocalcitonin and Parathyroid Hormone on the Levels of Calcium and (Prof. G. Milhaud and Dr. M. S. Moukhtar), 1186
Phosphate and Respiration in Nuclear Damage in Irradiated Rat Thymocytes: Role of (J. F. Whitfield and T. Youdale), 212
Phosphate from Shells of some Living Crustaceans: Oxygen Isotopic Composition of (A. Longinelli and M. Sordi), 727
Phosphate Uptake Studies with Plant Roots: Microbial Factor in Short-term (G. D. Bowen and Dr. A. D. Rovira), 665
Phosphatidyl Carnitine: a Possible Intermediate in the Biosynthesis of Phosphatidyl β-Methylcholine in *Phormia regina* (Meigen) (H. M. Mehendale, W. C. Dauterman and Dr. E. Hodgson), 759–61
Phosphides of Niobium, Tantalum and Tungsten: New Metal-rich (Dr. S. Rundqvist), 847
Phosphokinase: Effect of Insulin on Purified Creatine (Dr. R. B. Conn, jun.), 195
Phospholipids with Cholesterol: Nuclear Magnetic Resonance Spectroscopic Studies of the Interaction of Phospholipids with Cholesterol (D. Chapman and S. A. Penkett), 1304
Phospholipids from *Corynebacterium diphtheriae* P.W.8: Purification and Chemical Constitution of the (N. Ferreira Gomes, T. Ioneda and Dr. J. Pudles), 81
Phospholipids and Phosphoproteins of Nerve Endings of Developing Rat Brain: Acetylcholine and the Incorporation of [^{32}P] Phosphate into (Dr. A. A. Abdel-Latif), 530
Phosphonolipid by Larvae of the Housefly, *Musca domestica*: Formation of a (R. G. Bridges and J. Ricketts), 199
Phosphoproteins of Nerve Endings of Developing Rat Brain: Acetylcholine and the Incorporation of [^{32}P] Phosphate into Phospholipids and (Dr. A. A. Abdel-Latif), 530
Phosphoramidothionates: Biological Activity of (Dr. H. Tolkmith), 522
Phosphorus-32: Determination of Regional Blood Flow by means of Small Semiconductor Detectors and Red Cells tagged with (Dr. G. Grängsjo *et al.*), 1411
Phosphorylase B: Spectroscopic Evidence of Allosteric Effects in (S. Bresler et *al.*), 1262
Phosphorylation, Impairment of Oxidative, by D-threo- and L-threo-Chloramphenicol (Prof. J. B. Hanson and W. A. Krueger), 1322
Phosvitin: Optical Rotatory Dispersion of (Dr. G. E. Perlmann and Dr. S. E. Allerton), 1089
Photochemical Carboxylation: Reactivity of Excited Water Molecules in (Dr. N Getoff), 408
Photochemistry of the S-Nitroso Derivatives of Hexane-1-thiol and Hexane-1,6-dithiol (Dr. J. Barrett, L. J. Fitzgibbons, J. Glauser, Dr. R. H. Still and P. N. W. Young), 848
Photoelastic Behaviour of Sodium Nitrate (T. S. Narasimhamurty), 401
Photographic Atlas of the Moon (Prof. Z. Kopal), *review* by L. Wilson, 14
Photographic Plates used in Mass Spectrometry: Suppression of Halo on (Dr N. W. H. Addink), 1168
Photography of Mars: Implications of the *Mariner IV* (Dr. G. J. H McCall), 1384
Photography of the Moon and Mars: Origin of Meteorites, in the Light of Recent Rocket (Prof. G. Mueller), 1134
Photolysis of Iodine in the Continuum of the $\overline{B^3\Pi_{0u}^+}$—$X^1\Sigma_g^+$ System, and by Collisional Release inside the Banded Region Reaction with Propane of $I(5^2P_{1/2})$, produced by (Dr A. B Callear and J. F. Wilson), 517
Photolytic Degradation of Textile Fibres in the Far Ultra-violet (Dr. G. S. Egerton, E. Attle and M. A. Rathor), 1087
Photon Fluxes during the Solar Approach of the Ikeya-Seki Comet: Observations of the Low-energy (P. T. Gronstal and R. P. Bukata), 176
Photo-oxidation of Organic Matter in Sea Water by Ultra-violet Radiation, Analytical and Other Applications (F. A. J. Armstrong, P. M. Williams and J. D. H. Strickland), 481–3
Photopic Sensitivity in Chicks: Provitamin A_2: Electroretinographic Measurements of its Effect on (E. Auerbach et *al.*), 77
Photoreceptive Features of Vesicles associated with the Nervous System of Cephalopods (R. S. Nishioka, I. Yasumasu and H. A. Bern), 1181
Photo-sensitivity of Spermatozoa: Effects of Temperature on (C. van Duijn, jun., and J. H van Lierop), 1313–5
Photosynthesis: Liquid Scintillation Method for measuring Carbon-14 Uptake in (D. W. Schindler), 844
Photosynthesis and Uptake of Strontium-85 in Freshwater Plankton (Dr. B. C. Patten and R. L Iverson), 96
Phoxinus phoxinus L.: Effect of Spinal Lesions on the Colour Change of the Minnow, (Dr. D. Burton), 992
Physical Methods in Structural Chemistry: Newer, Symposium at Oxford (R. Bonnett), 688
Physical Oceanography: Elements of (Prof H. J. McLellan), *review* by Prof. K. F. Bowden, 911
Physical Research in Africa, 1334
Physicochemical Properties of Mitochondrial and Nuclear Deoxyribonucleic Acid from Rat Liver Cells: Comparison of (T. B. Kazakova and K. A. Markosian), 79
Physics: Data for, 110, 112
Feynman Lectures on (Prof. R. P. Feynman, Prof. R. B Leighton and Prof. M. Sands), Three Volumes, *review* by S. Weintroub, 123
Liquid State (Prof. H. N. V. Temperley), 906–8
Philosophical Foundation of (R. Carnap), *review* by R. G. Swinburne, 1235
Plasma, *review* by G. Rowlands, 1346
Successful, 223
Theory of Groups in Classical and Quantum (T. Kahan et *al.*), Vol. I, *review* by Dr. B. L. Moiseiwitsch 346
Physics of the Earth's Upper Atmosphere (edited by C. O. Hines, I. Paghis, T. R. Hartz and J. A. Fejer), *review* by Dr. P. C. Clemmow, 459
Physics of Elementary Particles (Dr. H. Muirhead), *review* by Prof. E. H. Bellamy, 234
Physics Information Exchange (PIE) Unpublished Literature, 333
Physics, Institute of, and the Physical Society: Presidential Address by Sir Gordon Sutherland, How to Spend Money? 792
Physics of Musical Sounds (Prof. C. A. Taylor), *review* by Dr. J. R. Pierce, 122
Physics and Nuclear Chemistry: Dictionary of Nuclear (edited by H. Rau), Second Edition, *review* by Dr. J. B Sykes, 462
Physiologie von Naturstoffen Beitrage zur Biochemie und, *review* by Prof. F. G. Young, 687
Physiology of Human Survival (edited by O. G. Edholm and A. L. Bacharach), *review* by Wing-Cmdr. J. Ernsting, 799
Physiology: Respiration, 901
Textbook of Aviation (edited by J. A. Gillies), *review* by Prof. A. D. M. Greenfield), 1235
Phytochrome in Callus Tissue of *Nicotiana tabacum* L.: Biological Detection of (Dr. M. J. Kasperbauer and Dr. R. A. Reinert), 744
Phytophagous Insect (*Caraterus morosus*): Neural Fat-body Sheath in a (Dr. S. H. P. Maddrell and Dr. J. E. Treherne), 215
Phytophthora infestans: Production of Pectic Enzymes by (Dr. D. D. Clarke), 649
Pickett, Prof. M. J., and Klasky, S.: Electrophoretic Determination of Albumin/Globulin Ratios in Mice, 1298–1300
Picrolonic Acid as a Hatching Agent for the Potato Cyst Nematode, *Heterodera rostochiensis* Woll. (Dr. A J. Clarke and Dr A. M. Shepherd), 546

Pieroni, Robert E., and Levine, L.: Adjuvant Principle of Pertussis Vaccine in the Mouse, 1419
Piezoelectric Crystal: Modulation of Diffracted Neutrons with a (Prof. T. F. Parkinson and M. W. Moyer), 400
Piezoelectric Effect in Poly-γ-methyl-L-glutamate (Prof. E. Fukada, M. Date and N. Hirai), 1079
Pigment Epithelium-Choroid Complex of the Eye of the Toad: An Earlier Phase of the Light-evoked Electrical Response from the (Dr. K. T. Brown and Dr. P W. Gage), 155–8
Pigment Spots of *Enoplus communis*: Chemical Nature of the (N. A. Croll), 859
Pigmentation in Bananas. Bract (W. G. C. Forsyth and K. S. Hamilton), 325
Pigmented Spots in Hamsters: Effect of Oestrogen on the Small (Dr. O. Illman and Dr. F. N. Ghadially), 1303
Pigments: Electron Microscopic Observation of Coatings on Titanium Dioxide (H. Smith), 292
Pigs to Infection with *Schistosoma haematobium* from Egypt: Susceptibility of (Dr. M. F. A. Saoud), 305
Pilkey, O. H., et *al.*. Sediment Transport by the Antarctic Bottom Current on the Bermuda Rise, 611
Pillow Structure in Lavas: Origin of (M. Solomon), 399
Pinched Lightning Discharges (Dr. C. E. R. Bruce), 62
Pine, Dr. C. S. F.: Analysis of Volatile Substances in Samples containing Non-volatile Substances by Process Gas Chromatography, 845
Pineal Sympathetic Nerve Processes and Endings to Angiotensin: Response of (Dr. N. M. Panagiotis and Prof. G. F Hungerford), 374–6
"Pink Spot": Identity of the (C. E. Bell and Dr. A. R. Somerville), 1405
"Pink Spot" and Schizophrenia (Dr. A. A. Boulton and C. A. Felton), 1404
Pinneo, Dr. Lawrence R.: Electrical Control of Behaviour by Programmed Stimulation of the Brain, 705–8
Pinocytotic Vesicles Extrusion of ATPase Activity from (Dr. C. A. Santos-Buch), 600–2
Pituitaries on Incubation *in vitro*: Dissociation between Antidiuretic and Vasopressor Activity in Rat Posterior (E. van Kammen and Prof. D De Wied), 93
Pituitary Glands of Rats: Some Effects of Certain Naturally Occurring Oestrogens on the Anterior (E. Stevens and J. E. Helfenstein), 879
Plane Fluid Film subjected to Normal Sinusoidal Excitation: Pressure Distribution in a (Dr. J. B. Hunt), 1437–9
Planet Uranus: History of Observation, Theory and Discovery (Dr. A. F. O'D. Alexander), *review* by S. Weintroub, 346
Plankton: "Living Fossils" in Western Atlantic (Dr. D. Wall and B. Dale), 1025
Plankton. Photosynthesis and Uptake of Strontium-85 in Freshwater (Dr. B. C. Patten and R. L. Iverson), 96
Plant Roots: Microbial Factor in Short-term Phosphate Uptake Studies with (G. D. Bowen and Dr A. D. Rovira), 665
Plant Terpenoids: Meeting at Aberystwyth (Dr. J Friend), 1128
Plants: Presence of a Series of Plastoquinones in (Dr. W. T. Griffiths et *al.*), 1037–9
Plasma produced by Adenosine Diphosphate and Adrenaline: Secondary Clumping Effect in Human Citrated Platelet-rich (Dr. D. C. Macmillan), 140–4
Plasma Clots and Gluconate: *In vivo* Fibrinolysis with a Dialysable Constituent of Recalcified Human (Prof. P. H. Kopper), 43
Plasma: Co-operative Scattering of Laser Light by a Thetatron (D. E. Evans et *al.*), 23
Plasma Diagnostic Techniques (edited by R. H. Huddlestone and S. L. Leonard), *review* by Dr. D. D. Burgess, 1022
Plasma Growth Hormone Level in the Monkey following the Administration of Sheep Hypothalamic Extracts: Increase in (Dr. J. F. Garcia and Prof. I. I. Geschwind), 372–4
Plasma Lipids: Liver Transplantation Effects on Canine (W. S. Worth et *al.*), 78
Plasma Physics, Lectures, *review* by G. Rowlands, 1346
Plasma Protein-bound Iodine Assay: Recoveries of Iodine-131-labelled Iodoamino-acids in the (Dr. M. W. O'Halloran and M L. Welby), 1195–7
Plasma and Spleen of Infected Mice: Distinctive Behaviour of *Eperythrozoon coccoides* in (Dr. P. G Stansly and C. F. Neilson), 1203
Plasminogen Activator in Saliva of the Vampire Bat *Desmodus rotundus* (C. Hawkey), 434
Plasmodium chabaudi-infected White Mice to a Fulminating and Fatal Strain of *Plasmodium vinckei*: Resistance of (Prof. M. Yoeli et *al.*), 49–51
Plasmodium vinckei Observations on the Gametogenesis of (Dr. J. Bafort et *al*), 439
Plastic Methods of Structural Analysis (Prof. B. G Neal), Second Edition, *review*, 570
Plastoquinones in Plants: Presence of a Series of (Dr W. T. Griffiths, J. C. Wallwork and Dr. J. F. Pennock), 1037–9

Platelet Aggregation in the Variable-frequency Thromboviscometer (M. C. Rozenberg and L. Dintenfass), 525–7
Platelet-rich Plasma produced by Adenosine Diphosphate and Adrenaline: Secondary Clumping Effect in Human Citrated (Dr. D. C. Macmillan), 140–4
Platelets: An Estimate of the Number of Adenosine Diphosphate Binding Sites on Human (Dr. J R. Hampton and Dr. J. R. A. Mitchell), 245
Plates: Conversion of Phenothiazine Derivatives to the Corresponding Sulphoxides on Thin-layer (J. Kofoed *et al.*), 147–50
Plating Solutions: Dissociation of Sodium Carbonate and Sodium Sulphite in Alcohol (W. Parker and W. Gullholmer), 1142
Platinum. Chloro-olefine Complexes of (W. J. Bland and Dr. R. D. W. Kemmitt), 963
Platinum Electrode: Rapid Voltammetric Determination of Methionine with a (D. Kyriacou), 519–21
Platner, Prof. W. S., and Bopp, J. R.: Effects of Cold Stress on Serum Protein Fractions of the Prairie Meadow Mouse, 634
Pleistocene Events in South-west Wales: Dating (Dr. D. Q. Bowen), 475
Plerocercoids in the Trout *Salmo trutta* L. of Llyn Padarn, Caernarvonshire: Decline in the Occurrence of *Diphyllobothrium* (A. M. Powell and Dr. J. C. Chubb), 439
Ploidy: Copulation of Ultra-violet-irradiated and Unirradiated *Saccharomyces* Cells of Different (K. Haefner and H. Kirschfeld), 310
Plurivesicular Nerve Endings in the Pulmonary Artery (Dr. M. A. Verity, J. A. Bevan and R. J. Ostrom), 537
Plutonic Intrusives on Cape Colville Peninsula and Cuvier Island, New Zealand: Potassium–Argon Age of (Dr. J. R. Richards *et al.*), 725
Podzol Jubilee, 557
Poison, Paralytic Shellfish (Dr. H. M. Johnson and Dr. G. Mulberry), 747
Poland: Sixteenth Pugwash Conference in Sopot, 1331
Polar Atmosphere from Infrasonic Observations of the Eruption of an Alaskan Volcano: Evidence of Two Sound Channels in the (C. R. Wilson *et al.*), 163–5
Polarity of the Earthquake Source (Dr. F. F. Evison), 273–5
Polarized Light Responses from Crab Retinula Cells (S. R. Shaw), 92
Polenov, Prof. A. L., and Senchik, J. I.: Synapses on Neurosecretory Cells of the Supra-optic Nucleus in White Mice, 1423
Policeman: The Existence of the Crossroads (J. Shotter), 343–5
Policy for Science. Is it Possible? 1221
Polin, D., Kelley, K., Lehman, E., and Ott, Dr. W. H. Tolerance of Chickens to Thiabendazole, 753
Poliovirus Marker Studies of (Y. E. Cossart), 1432
Poljanskij, J. I., *et al.*: General Protozoology, Revised Second Edition, *review* by Prof. P. C. C. Garnham, 126
Polkey, C. E., *et al.*: Effect of Muscle Loading on the Behaviour of Interneurones in the Lumbar Spinal Cord, 425
Pollak, F. M.: Esterase Activity in the Arachnida, 546
Pollen and Spore Morphology/Plant Taxonomy—Gymnospermae, Bryophyta (Text) (Prof. G Erdtman) Introduction to Palynology III, *review* by Dr. W. G. Chaloner, 16
Polonium-210 in Human Blood: Measurement of (Dr. J. B. Little and Dr. R B. McGandy), 842
Poly-acids Determination of the Sodium bound by (V. Palaty), 1177
Polyanions. Inhibition of Neuraminidase by (R. Drzenick), 1205
Polyarteritis Nodosa-like Disease in Outbred Mice (R. D Wigley and K. G. Couchman), 319
Poly-β-benzyl-L-aspartate: Structural Changes in (B. M. Watson, D. B. Green and Dr. F. Happey), 1394
Polychaetes Non-associative Behavioural Modifications in Nereid (Dr. S. M. Evans), 945–8
Polycyclic Aromatic Hydrocarbons: Losses due to Adsorption during Filtration of Aqueous Solutions of (Dr. M. N. Inscoe), 1083–5
Polycyclic Carcinogens and Nucleic Acid Bases Electron Spin Resonance Examination of Charge Transfer Complexes of (Dr. J. B. Jones *et al.*), 309
Polyethylene and Polytetrafluoroethylene: Adsorption of Caesium Tetraphenylborate from Aqueous Solutions on Glass, (I. A. Skul'skii and V. V. Glasmov), 631
Polyhaploid Plant in an Autotetraploid Variety of Sugar Beet: Self-fertile (Dr. M. Rommel), 648
Polymer Additives on Boundary Layer Separation and Drag of Submerged Bodies: Effect of (A. White), 1390
Polymer Crystallization: Orientation-induced Nucleation in (Dr. F. L. Binsbergen), 516
Polymers: Interpretation of Electrolyte Invasion Data for Ion-exchange (C J Attridge), 1293
Polymers: Vol. 1: Testing of (edited by J. V. Schmitz), *review* by Prof. C. E. H Bawn, 1346
Poly-γ-methyl-L-glutamate: Piezoelectric Effect in (Prof. E. Fukada *et al.*), 1079
Polymethyl Methacrylate: Electron Spin Resonance Studies of the Reactions of Nitric Oxide and Nitrogen Dioxide with (J. Law), 1351–4
Polymethyl Methacrylate at 30°–32° C: A Lower Transition Point for (Prof. H. F. Atkinson and Dr. A. A. Grant), 627
Polymorphic Forms of the Diaminopyrene-*p*-chloranil and Related Molecular Complexes (Dr Y. Matsunaga), 183
Polymorphisms: Maintenance of Histocompatibility (Dr. B. Clarke and Dr. D. R. S. Kirby), 999
Polyoma Tumour Homografts: Effect of Thymectomy on Transplantation Resistance induced by (R. C. Ting), 1000
Polyoma Virus. Infection of Thymidine Kinase-deficient *BHK* Cells with (Dr. J. W. Littlefield and Dr. C. Basilico), 250–2
Polypeptide Chains of Haemoglobin: Sequence of Linkage between the Prosthetic Groups and the (Dr. K. H. Winterhalter), 932–4
Polypeptide Hormone Production: 5-Hydroxytryptophan Uptake by Dog Thyroid 'C' Cells, and its Possible Significance in (Prof. A. G. E. Pearse), 598–600
Polypeptide Synthesis directed by a Bacteriophage Ribonucleic Acid in a Cell-free System (Dr. B. F. C. Clark and Dr. K. A. Marcker), 378–80
Polypeptidyl-*s*Ribonucleic Acid and Amino-acyl-*s*Ribonucleic Acid Binding Sites on Ribosomes (M. S. Bretscher and Dr. K. A. Marcker), 380–4
Polypropylene: Interior Morphology of Bulk (Dr. K. D. Pae *et al*), 514
Polysomes by the *N,N*-Dimethyl-*p*-methoxy-L-phenylalanyl Analogue of Puromycin: Release of Peptide Chains from Rat-liver (A. O Hawtrey and Miss S. I. Biedron), 187–9
Polytetrafluoroethylene: Adsorption of Caesium Tetraphenylborate from Aqueous Solutions on Glass, Polyethylene and (I. A. Skul'skii and V. V. Glasmov), 631
Polythene subjected to Partial Discharge: Changes in Loss Tangent of (A. W. Stannett and R. A. MacKenzie), 626
Poly-2-vinylpyridine-1-oxide with Silicic Acid: Interaction of (Dr P. F. Holt and E. T. Nasrallah), 878
Pompeiano, O., and Morrison, A. R.: Response of Alpha Motoneurones to Direct Electrical Stimulation during Desynchronized Sleep, 636
Ponnamperuma, F. N., and Yuan, W L.: Toxicity of Boron to Rice, 780
Pontecorvo, Prof. G.: General Genetics, Second Edition, *review*, 18
Poole, E. G.: Late Weichselian Glaciation in the Cheshire–Shropshire Basin, 507
Popper, K., Camirand, W. M., Stanley, Dr. W. L., and Nury, F. S.: Osmotic Emergency Purifier of Sea Water, 297
Population Conference in Strasbourg: Demographic Revolution, 1333
Population Dynamics of the Blackbird (Dr. D. W. Snow), 1231
Population Excursions, 901
Population and Land Problems: Forty Million Englishmen? 1007
Population: Land and Human (Sir Joseph Hutchinson), 1053–5
Porai-Koshits, E. A., and Toropor, N. A. (edited by) Structural Transformations in Glasses at High Temperatures (Structure of Glass, Vol. 5), *review* by Prof. R. W. Douglas, 124
Porous Carbons: New Evidence for the Fine Structure of (A. Bailey and Prof. D. H. Everett), 1082
Porphyria induced in Rats by Ethionine: Experimental (A. Palma-Carlos, L. Palma-Carlos, M. Gajdos-Torok and Dr. A. Gajdos), 977
Porphyria induced in Rats by Orotic Acid and the Effect of Adenine-5′-monophosphoric Acid (Dr. A. Gajdos, M. Gajdos-Török, A. Palma-Carlos and L. Palma-Carlos), 974
Portal Blood: Thyrotrophin Releasing Factor in Hypophyseal (Dr. R. L. W. Averill *et al.*), 144
Porter: Prof. George Director of the Royal Institution, 1009
Positronium and Structure of Fundamental Particles: Relativistic States of (Dr. P. F. Browne), 810–3
Posner, Dr. Aaron S., and Termine, J. D.: Infra-red Determination of the Percentage of Crystallinity in Apatitic Calcium Phosphates, 268–70
Pospíšilová, Dr. J.: Effect of Peroxides on the Hydration Elongation of Rat Tail Tendon, 536
Post Office (British): Swings and Roundabouts, 450, Parliament in Britain, 673
Postglacial Land Uplift in Northern Ungava, Canada: Radiocarbon Dated (B. Matthews), 1164–6
Post-irradiation Oxygen Deprivation Prevention of Nuclear Damage in Irradiated Rat Thymocytes by (Dr. J. F. Whitfield and Dr. H. Brohee), 775
Post-irradiation Textural Changes in Fruits and Vegetables: Radiation induced Calcium Release and its Relation to (Dr. J. Shah), 776
Postnatal Period: Effect of Reduced Glutathione on Haem Synthesis during the (W. Schröter and A. Oole), 1406
Potassium–Argon Age of Plutonic Intrusives on Cape Colville Peninsula and Cuvier Island, New Zealand (Dr J. R. Richards, J. A. Cooper and P M. Black), 725
Potassium–Argon Measurements of the Age of Basal Schists in the British Solomon Islands (Dr. J. R. Richards, J. A. Cooper, A. W. Webb and Dr. P. J. Coleman), 1251
Potato Cyst Nematode, *Heterodera rostochiensis* Woll.: Picrolonic Acid as a Hatching Agent for the (Dr. A. J. Clarke and Dr. A. M. Shepherd), 546
Potential: Two Components of the Cardiac Action (Prof. A Paes de Carvalho *et al.*), 938–40
Potentials: Glass Microelectrodes: the Origin and Elimination of Tip (Prof D. Agin and D. Holtzman), 1194
Potentials of Metallic Powder Formation on the Mercury Dropping Electrode (Dr. A Calusaru and Dr J. Kuta), 1080
Pound for a Pound? Decimal Currency, 1112

Power for *Dragon*. More, 788
Poydock, Sr M. E., *et al.*: Effect of Magnetic Fields on the Respiration of Malignant, Embryonic and Adult Tissue, 433
Poynter, Dr. F. N. L.: Benjamin Franklin and Eighteenth-Century American Libraries, *review*, 1234
Prairie Meadow Mouse: Effects of Cold Stress on Serum Protein Fractions of the (J. R. Bopp and Prof. W. S. Platner), 634
Pratt, H. K., *et al.*: Production of Carbonyl Compounds by Tomato Fruit Tissue in the Presence of Aliphatic Alcohols, 419
Precipitation, Effect of, on Transmission through the Atmosphere at 10 Microns (R. W. Wilson and A. A. Fenzias), 1081
Precursor–Product Relationship between Nuclear and Cytoplasmic Ribonucleic Acid (U. N. Singh and R. Koppelman), 75–7
Prediction of Eclipses (D. H. Sadler), 1119–21
Predictor: Stonehenge—an Eclipse (Prof. F. Hoyle), 454–6
Prekeratin: Epidermal Keratin and Epidermal (Dr. R. G Crounse), 1301
Preprints Galore: Information Exchange Groups, 897, Correspondence (D. J. B. Copp), 1116
Prescott, R., and Standage, Dr. A. E.: High Elastic Modulus Carbon Fibre, 169
"Preservative" for Living Holothurians: Propylene Phenoxetol as a (Dr. R B. Hill), 304
Pressure Distribution in a Plane Fluid Film subjected to Normal Sinusoidal Excitation (Dr. J. B. Hunt), 1137–9
Pressure Wave from an Explosion: Atmospheric (Dr. Bhartendu and Dr. R. McCrory), 396–8
Pressures: Far Infra-red Spectroscopy at High (Dr. C. C. Bradley *et al.*), 839
Priapulid from Northern Labrador: Relict (J. C H. Carter), 438
Probability and Utility: Classification, (Dr. D. W Goodall), 53
Probe Data: Comparison of Electron Temperature with Thermosphere (Dr. R. N. Singh and S. K. Tolpadi), 1167
Probe for the Measurement of Metastable Nitric Oxide in the Upper Atmosphere: Laser Radar (L. J. Nugent), 1349–51
Problem-solving Skill: Simulation of a Perceptual (Dr. A. E. Elithorn *et al.*), 1029–31
Problems in Quantum Mechanics: Selected (collected and edited by D ter Haar), Revised and Augmented Second Edition, *review* by Dr. F. H. Read, 801
Process Plant Radioiodine Vapour Snow and Rain Washout Coefficients for (R. J Engelmann and R. W. Perkins), 61
Programme for Automatic Scanning of Autoradiographs and Microradiographs of Bone Sections: Computer (Dr. E. Lloyd *et al.*), 661
Programming, Games and Transportation Networks (Prof. C. Berge and Prof. A. Ghouila-Houri), *review* by Dr. H. O. Foulkes, 1125
Programming for Rain: Kinematic (M. Stone), 442
Project for Engineers: New Magazine by Department of Education and Science, 4
Propane, Reaction with, of $1(5^3P_{1/3})$, produced by Photolysis of Iodine in the Continuum of the $B^3\Pi_{0u}^+—X^1\Sigma_g^+$ System, and by Collisional Release inside the Banded Region (Dr. A. B Callear and J. F. Wilson), 517
Propionate-grown *Prototheca zopfii*: Level of Vitamin B_{12} in (Dr. D. Lloyd), 765
Propylene Phenoxetol as a "Preservative" for Living Holothurians (Dr. R B. Hill), 304

Prostatic Carcinoma and Multiple Myeloma: Electrophoretic Separation of Serum Acid Phosphatase Isoenzymes in Gaucher's Disease, (Dr. A. F. Goldberg *et al.*), 41–3
Prosthetic Groups and the Polypeptide Chains of Haemoglobin: Sequence of Linkage between the (Dr. K. H. Winterhalter), 932–4
Protective Effect of Some Neutral Solutes on the Inactivation of Myosin A-Adenosine Triphosphatase (Y. Hashimoto and Prof. T. Yasui), 194
Protein (Antibodies) with the Deoxyribonucleic Acid Molecule: Interactions of (Dr. A. M. Poverenny, A. S. Saienko, V. G. Kreier and V. A. Nasonova), 1297
Protein Binding of Iodine-131 in the Presence of Iodate: Anomalous (W. T. Baker and G. Owen), 641
Protein-bound Iodine Assay: Recoveries of Iodine-131-labelled Iodo-amino-acids in the Plasma (Dr M. W. O'Halloran and M. L. Wellby), 1195–7
Protein Biosynthesis. *N*-Formyl-methionyl-sRibonucleic Acid and Chain Initiation in (Dr. B. F. C. Clark *et al.*), 378–84
Protein Complex from Bovine Intervertebral Disks: Isolation of a Chrondroitin Sulphate (Dr. D. A. Lowther and E. Baxter), 595–7
Protein Content of Young Barley Seedlings: Effect of Cycocel and its Analogues on Growth and Soluble (Dr. A. A. Khan and M. A. Faust), 1215
Protein from Crayfish Nerve: Actomyosin-like (Dr. K. Bowler and Dr. C. J Duncan), 642
Protein-disulphide Reductase Activity in Yeast (C. M. Brown and Dr J. S. Hough), 201
Protein under Electron Bombardment: Fission of Virus and (Dr. L. Jacob), 633
Protein Fractions of the Prairie Meadow Mouse: Effects of Cold Stress on Serum (J. R. Bopp and Prof. W. S. Platner), 634
Protein. Immunological Tolerance of the Female to Homologous Seminal Plasma (J. O. Menzoian and Dr. M. M Ketchel), 133–5
Protein Synthesis by *Cycloheximide* (Actidione) in *Chlorella*: Inhibition of (I. Morris), 1190–2
Protein Synthesis: Monovalent Cation Requirement for the Aminoacyl Transfer Reaction in (H. Levine *et al.*), 1302
Protein Synthesis and Water Uptake by Kinetin Uncoupling of Auxin-induced (D. Banerji and Dr. M. M. Laloraya), 758
Proteins: Effect of Dipicolinate on the Heat Denaturation of (Y Mishiro and M. Ochi), 1190
Elimination of Non-specific Antibodies from Rabbit Antisera using Acetone-precipitated Soluble (B. Schmidt *et al.*), 32
Incorporation of Histamine Ribonucleoside into Soluble (Prof. S. G. A. Alivisatos *et al.*), 187
Separation of Connective Tissue Mucopolysaccharide–Protein Complexes from Unrelated (E. R. Berman), 640
Solubility-composition Relations of Gluten (M. V. Tracey), 850
Proteins from Chromaffin Granules of Ox, Horse and Pig: Studies on the (Dr. H. Winkler, E. Ziegler and N Strieder), 982
Proteins and the Extent of Amino-acid Recycling: Use of Carbon-14-labelled Arginine to measure the Catabolic Rate of Serum and Liver (Dr. J. M. L. Stephen and Prof. J C. Waterlow), 978–80
Proteins and Surface Films. Ice Nucleation by (L. F. Evans), 281
Proteus: Swarming of, —a Solution to an Old Problem? (Dr. R. B. Morrison and Dr. A. Scott), 255–7
Proteus–Providence Group: Specific Activity of Phenylalanine Deaminase in Extracts of the (Dr. J. A. Smit), 1003
Proton Impact with Special Reference to the Lunar Surface: Luminescence caused by (J Schutten and Th. Van Dijk), 470 (J E. Geake and G. Walker), 471
Proton Microanalysis (B. K. Mak, Dr. J. R. Bird and T. M. Sabine), 738
Proton Nuclear Magnetic Relaxation Investigations of Water (Prof. R. E. Glick and K. C. Tewari), 739
Prototheca zopfii: Level of Vitamin B_{12} in Propionate-grown (Dr. D. Lloyd), 765
Utilization of Adenine but not Nitrate as Nitrogen Source by (J L. Stacey and Dr. P. J. Casselton), 862
Protozoology: General (V. A. Dogiel, revised by J. I. Poljanskij and E. M. Chejsin), Second Edition, *review* by Prof. P. C. C. Garnham, 126
Prout, Prof E. G., and Nassimbeni, L. R.: Crystal Structure of Caesium Permanganate, 70
Provitamin A_3: Electroretinographic Measurements of its Effect on Photopic Sensitivity in Chicks (E. Auerbach, H. Rowe and P. Budowski), 77
Proximity of Cooling Towers to Each Other: Wind Forces and the (Dr. P. W Bearman), 735
Prudnikov, A P., and Ditkin, V. A.: Integral Transforms and Operational Calculus, *review* by Dr. M. A. Jaswon, 235
Prusoff, Prof. William H , and Sekely, Dr. L.: Anti-viral Activity of Azathymidine and Uracil Methyl Sulphone, 1260
Psammechinus miliaris: Purification and Characterization of Ribonuclease from Unfertilized Eggs of the Sea Urchin (P. Fernlund and Prof L Josefsson), 1402
Pseudomonadaceae and Enterobacteriaceae: D-Glucarate Catabolism by (Dr. P. W. Trudgill and R. Widdus), 1097–9
Pseudorutile—a New Mineral Intermediate between Ilmenite and Rutile in the Natural Alteration of Ilmenite (Dr. G. Teufer and A. K. Temple), 179–81
Psocid Genera (Psocoptera): Chromosome Numbers of some (Miss S. K Wong and Dr. I. W. B. Thornton), 214
Psocoptera Chromosome Numbers of some Psocid Genera, (Miss S. K. Wong and Dr I W. B Thornton), 214
Psychological Stress: Vertical Sinusoidal Vibration as a (H. F. Huddleston), 324
Psychology: The Nature of (K. J. W. Craik), (edited by S. L. Sherwood), *review* by Prof C Burt, 462
Psychoyos, Alexandre: Influence of Oestrogen on the Loss of the Zona Pellucida in the Rat, 864
Pudles, Dr J , *et al*: Purification and Chemical Constitution of the Phospholipids from *Corynebacterium diphtheriae* P.W 8, 81

Puett, D , Garmon, R., and Ciferri, A Role of Neutral Salts on the Denaturation Temperature of Biopolymers, 1294
Puget Sound Earthquake of April 29, 1965 Micropulsation Measurements during the (J. F. Kenney and L. E. Johnson), 1041–3
Pugwash after Pugwash, 1330, Pugwash in Sopot, Poland, 1331
Pullet: Re-investigation of the Effects of 'Nilevar' on the Right Gonad of the (Dr. H A. Wood, jun., *et al.*), 536
Pulmonary Artery: Plurivesicular Nerve Endings in the (Dr. M. A. Verity *et al*), 537
Pulse Radiolysis Investigations of Unimolecular Elimination Reactions in Free Radicals produced by OH Addition to Hydroxybenzenes (Dr. G E Adams, B. D Michael and Dr E J. Land), 293
Pulse Technology. High Speed (Dr F B. A Frungel), Vol. I, *review* by Prof D. Gabor, 350
Pulses from Jupiter: Millisecond Radio (Dr. E. E. Baart *et al.*), 808–10
Pumps: Simple Allosteric Model for Membrane (Dr. O. Jardetzky), 969
Purifier of Sea Water: Osmotic Emergency (K Popper *et al.*), 297
Purine and Pyrimidine Bases on 'Ectaola' Cellulose at Room Temperature and Elevated Pressure: Rapid Column Chromatography of (S. P. Kelemen and E. T. Degens), 857–9
Puromycin on Chromosomes of Cultured Human Leucocytes: Effects of Actinomycin *D* and (R. L. Neu *et al.*), 881
Puromycin: Release of Peptide Chains from Rat-liver Polysomes by the *N,N*-Dimethyl-*p*-methoxy-L-phenylalanyl Analogue of (A. O. Hawtrey and Miss S. I. Biedron), 187–9
Purpura, Dr. Dominick P.: Activation of "Secondary" Impulse Trigger Sites in Hippocampal Neurones, 1317
Pyke, Dr. Magnus: International Nutrition, Meeting at Hamburg, 914
Pyridine $2I_2$ Complex in the Gas Phase: Evidence for the (R. Cahay and J. E. Collin), 1175
Pyrimidine Bases on 'Ectacla' Cellulose: Rapid Column Chromatography of Purine and (S. P. Kelemen and E. T Degens), 857–9
Pyrrhotite: a Common Inclusion in South African Diamonds (W. E. Sharp), 402
Pyrrhotite in an Electron Microscope. Decomposition of Ferrosic Sulphide to (M. Uda), 67

QUANTOCK, Dr. D. C., *et al.*: Effect of Orchidectomy and Ovariectomy on Survival Against Lethal Infections in Mice, 1091
Quantum Chemistry, Vol. 2: Advances in (edited by Per-Olov Löwdin), *review* by Prof. D. P. Craig, 1124
Quantum Chemistry: Methods of (M. G. Veselov), *review* by Prof. D. P. Craig, 1124
Quantum Efficiencies of Octa-co-ordinated Europium Homogeneous and Mixed Chelates in Organic Solvents: Fluorescence (Dr. N. Filipescu *et al.*), 960
Quantum Mechanics: Selected Problems in (edited by D. ter Haar), Second Edition, *review* by Dr. F. H. Read, 801
Quantum Physics: Theory of Groups in Classical and (T. Kohan *et al.*), Vol. I, *review* by Dr. B. L. Mciseiwitsch, 346
Quarks and Cosmology (W. E. Saslaw), 729
Quartz Paramagnetic Resonance Centres in Amethyst and Citrine (D. R. Hutton and G. J. Troup), 621
Quartz Sand: Formation of (Dr. I. J. Smalley), 476–9
Quasars: Cosmological Significance of the Relation between Red-shift and Flux Density for (Dr. D. W. Sciama and M. J. Rees), 1283
Inverse Compton Effect in (M. J. Rees and Dr. D. W Sciama), 805–7
Quasars and Other Radio Sources: Absorption of High-energy Gamma-rays within (Dr. J. V. Jelley), 472–5
Quasi-stellar Objects Identification of Radio Galaxies and (J. G. Bolton), 917–20
Quasi-stellar Radio Sources: Model of (Prof. P. A. Sturrock), 697–700
Quasi-stellar Sources Possible Galactic Origin for (G. J. Odgers and Prof. R. W. Stewart), 1284
Quaternary Aqueous Systems containing Bile Salt, Lecithin, and Cholesterol: Ternary and (D. M Small *et al.*), 816–8
Queen Elizabeth College of the University of London: Domestic into General Science at, 338
Quench Gap in Vacuum: Arc (Dr J. B. Rittenhouse), 504–6
Quesnel, Dr. Louis B.. Flagella-assisted Cell Fission in *Escherichia coli*, 659
Queue Length Distribution for some Queues with Correlated Inputs. Evaluation of the (Dr. T. Lewis), 1106
Quiet Magnetospheric Phenomena related to the Geomagnetic Tail: Theory of some (K. D. Cole), 1385–7
Quilliam, Prof. J. P , *et al*.. Modification of the Auditory Flutter Fusion Threshold by Centrally Acting Drugs in Man, 751
Quinn, Dr. James G., and Salomon, Dr. M : Hydrolysis of Soil Nitrogen by Strong Acids, 664
Qureshi, Prof. M. Munir, and Maybank, J.: Further Tests on the Ice Nucleation Potential of Meteoritic Material, 508

RABBIT Flea. Hormones of the Vertebrate Host Controlling Ovarian Regression and Copulation of the (the Hon. Miriam Rothschild and B. Ford), 261–6
Rabin, Dr. B R., *et al*. Mechanism of Action of Bovine Pancreatic Ribonuclease, 252–5
Rabinovich, Dr. D., and Schmidt, Prof. G. M. J. Direct Solution of Organic Crystal Structures from Molecular Packing Considerations, 1391–3
Rabinovich, Dr. Sergio, *et al*.: Chemical Treatments of Staphylococcal Infections in Mice, 720–2
Racial Contours: Factor of Race in Human Survival (H. B Isherwood), *review* by Prof. T. Dobzhansky, 120
Radar Probe for the Measurement of Metastable Nitric Oxide in the Upper Atmosphere: Laser (L J. Nugent), 1349–51
Radial Distribution Function from a Random Packing of Spheres. Fine Structure in the (Dr G. Mason and Dr W. Clark), 957
Radial Spread of a Liquid Stream on a Horizontal Plate (R. G. Olsson and E T. Turkdogan), 813–6
Radiation: Diurnal Variation in Organismic Response to Very Weak Gamma (Prof. F A. Brown, jun., *et al.*), 830–3
Evidence for a Two-way Sidereal Anisotropy in the Charged Primary Cosmic (R. M Jacklyn), 690–3
On the Origin of the Microwave Background (Dr. D. W. Sciama), 277–9
Quality of, 1334
Radiation, Analytical and Other Applications: Photo-oxidation of Organic Matter in Sea Water by Ultra-violet (F. A. J Armstrong *et al*), 481–3
Radiation in Aromatic Materials: Diffusion of Triplet Excitons produced by Ionizing (Dr K. Voltz *et al.*), 405
Radiation Damage in Graphite (J H. W. Simmons), *review* by Prof. G. E. Bacon, 125
Radiation Dose: Response to X-irradiation of a Tumour recurring after a TCD_{95} (Dr. H. D. Suit), 996
Radiation-induced Calcium Release and its Relation to Post-irradiation Textural Changes in Fruits and Vegetables (Dr J. Shah), 776
Radiation-induced Inhibition of Thymidine Incorporation by Mammalian Cells *in vitro* (Dr. L. A Smets), 527
Radiation-less Decay of Anthracene Triplet: Effect of Deuterium Substitution on (Dr A. Beckett), 410
Radiation on the Leaves of Higher Plants Effects of Ultra-violet alone and Simulated Solar Ultra-violet (Dr. M. G. Cline and Dr. F. B Salisbury), 484–6
Radiation on Murine Leukaemia Cells *in vitro*: Comparison of Direct and Indirect Effects of Alkylating Agents and (Dr. G. J. Goldenberg), 427
Radiation Recovery Response of Mammalian Tumour Cells *in vivo* (Dr J A. Belli, Prof. F. J Bonte and M S. Rose), 662
Radiation Sterilization of Sugar-cane Leafhoppers of the Family Delphacidae (Dr. E. Shipp, A. W. Osborn and P. B Hutchinson), 98
Radio Astronomical Detection of Helium (Prof. A. E. Lilley, P. Palmer, H. Penfield and B. Zuckerman), 174

Radio Aurorae: Thermospheric Energetics and a Possible Explanation of some Observations of Geomagnetic Disturbances and (Dr. R. E. Newell), 700–3
Radio Background: Origin of the Microwave (Prof. P. J. E. Peebles and Prof. R. H. Dicke), 574
Radio Bursts. Frequency Splitting of Solar (Prof. G. R. A. Ellis and P. M. McCulloch), 1070
Radio Communication: Method for Translunar (Dr. W. W. Salisbury), 950
Radio Emission from Galactic OH: Determination of Direction, Frequency and Polarization of (Dr. A. H. Cook), 503
Radio Emission of Venus at 3 cm and the Solar Activity (V. Letfus), 176
Radio Galaxies and Quasi-stellar Objects: Identification of (J. G. Bolton), 917–20
Radio Noise during a Total Solar Eclipse: Apparent Increase in Galactic (S. G. Kingan *et al.*), 950
Radio Pulses from Jupiter: Millisecond (Dr. E. E. Baart *et al.*), 808–10
Radio Sources: Absorption of High-energy Gamma-rays within Quasars and Other (Dr. J. V. Jelley), 472–5
Appearance of Relativistically Expanding (M. J. Rees), 468–70
Correlation between Peculiar Galaxies and (Dr. D. Lynden-Bell *et al.*), 838
Model of Quasi-stellar (Prof. P. A. Sturrock), 697–700
Model for Variable Extra-galactic (Prof. H. van der Laan), 1131–3
Radio Sources 3C 46, 66, 129 and 465: Structure of the (G. H. MacDonald, A. C. Neville and Sir Martin Ryle), 1241–4
Radio Sources in the 20–40 Mc/s Range: Spectra of Nine Discrete (D. A. Guidice), 57–9
Radiosources in the *Revised 3 C Catalogue*: Counts of (P. Véron), 724
Radioactive Fallout from Nuclear Weapons Tests (edited by A. W. Klement, jun.), A.E.C. Conference 1964, *review* by D. H. Peirson, 682
Radioactive Fossil Fish from Thurso, Scotland: Unusually (Dr. S. H. U. Bowie), 728
Radioactive Strontium following Contamination in Adult Men: Assessment of Body Content of (Dr. G. E. Harrison and Dr. J. Rundo), 774
Radiocarbon Dated Postglacial Land Uplift in Northern Ungava, Canada (B. Matthews), 1164–6
Radiofrequency-induced Gas Plasma at 250–300 Kc/s (I. J. Floyd, J. C. Lewis and R. K. Bayliss), 841
Radioiodine Vapour: Snow and Rain Washout Coefficients for Process Plant (R. J. Engelmann and R. W. Perkins), 61
Radiolysis of Aliphatic Alcohols: Primary Organic Radical formed in the (R. A. Basson), 629–31
Radiolysis of Aqueous Solutions of Di-ethyl Acetal: Reactions of the Hydroxyl Radical in the (Dr. R. A. Basson and P. M. Champion), 1398
Radiolysis Investigations of Unimolecular Elimination Reactions in Free Radicals produced by OH Addition to Hydroxybenzenes: Pulse (Dr. G. E. Adams *et al.*), 293
Radionuclides in Rainwater: Ion Exchange Method of estimating Strontium-90 and Other (C. Brenan *et al.*), 68
Radio-protection in *Saccharomyces*: Cysteine Incorporation and (Dr. V. Schaedel *et al.*), 431
Radioprotective Effectiveness of Compressed Gases: Comparative (V. P. Paribok and V. S. Kalney), 1428
Radiosensitivity and Repair: Meeting at Vienna (M. W. Miller and Dr. J. R. K. Savage), 240
Radiotherapy: Fast-neutron Source for (Dr. R. J. Berry and Dr. R. E. Ellis), 267
Radiothermoluminescence of 4,4'-Dimethylbenzophenone (N. S. Marans, F. Wessells and S. Olfky), 1176
Radium Content of Rainwater (P. Banerji and Prof. S. D. Chatterjee), 511
Radius. Implications of the Revised Mars (Prof. K. E. Bullen), 396
Radok, J. R. M., and Noye, B. J.. Southern Storm Centres and Ocean Wave Spectra, 287
Raghavan, S. R., and Balakrishna, Dr. S.: M_2 and S_2 Tidal Components at Hyderabad, 288
Railway: Channel Tunnel Submarine, 335
Railway Relics, 1116
Rain: Kinematic Programming for (M. Stone), 442
Rain Washout Coefficients for Process Plant Radioiodine Vapour: Snow and (R. J. Engelmann and R. W. Perkins), 61
Rainwater: Ion Exchange Method of estimating Strontium-90 and Other Radionuclides in (C. Brenan *et al.*), 68
Radium Content of (P. Banerji and Prof. S. D. Chatterjee), 511

Resistance of *Plasmodium chabaudi*-infected White Mice to a Fulminating and Fatal Strain of *Plasmodium vinckei* (Prof M. Yoeli, Dr R. Nussenzweig, Miss R. S. Upmanis and Prof. H. Most), 49–51
Resistance to Shearing of Heat-denatured Muscle in Relation to Shortening (B. B. Marsh and N. G. Leet), 635
Resistance *In vivo* Transfer of Infectious Drug (J. R Walton), 312
Resources: Conservation of Natural (edited by G.-H. Smith), Third Edition, *review* by Dr. W. J. Eggeling, 566
Respiration in Euphausiids (L. F. Small, J. F. Hebard and C. D McIntire), 1210
Respiration of Malignant, Embryonic and Adult Tissue: Effect of Magnetic Fields on the (Prof J. C. Fardon et *al.*), 433
Respiration in Nuclear Damage in Irradiated Rat Thymocytes: Roles of Phosphate and (J. F. Whitfield and T. Youdale), 212
Respiration Physiology, 901
Respiratory Activity of Guinea-pig Leucocytes: Effect of Disseminated Lupus Erythematosus Sera on the (A. E. Fruehan et *al.*), 1269–72
Respirometer using the Carbon-Dioxide Electrode. Diffusion-exchange (Dr. C. R. Jensen et *al.*), 608–10
Response of Alpha Motoneurones to Direct Electrical Stimulation during Desynchronized Sleep (A. R. Morrison and O Pompeiano), 636
Response of Crustacean Nerve Fibre in a Solution Deficient in Chloride Ions: Slow (Dr. T. Tomita and Prof. E B. Wright), 1100
Response of Pineal Sympathetic Nerve Processes and Endings to Angiotensin (Dr N. M. Panagiotis and Prof. G. F. Hungerford), 374–6
Response to Repeated Sensory Stimulation of Neurones in the Midbrain: Effect of Removing the Neocortex on the (Dr. G. Horn and R. M. Hill), 754
Response of Some Tomato Genes to Base-specific Mutagens: Differential (H. K. Jain and R. N. Raut), 652
Response to Very Weak Gamma Radiation: Diurnal Variation in Organismic (Prof. F. A Brown, jun., et *al.*), 830–3
Response to X-irradiation of a Tumour recurring after a TCD_{98} Radiation Dose (Dr. H. D Suit), 996
Responses from Crab Retinula Cells Polarized Light (S R Shaw), 92
Responses of *Drosophila* to Weak Magnetic and Electrostatic Fields: Some (H. D. Picton), 303
Retention of Cerium-144 by Beagles: Long-term *in vivo* (Dr. C. R Richmond and J. E London), 1179
Retina: Electro-optical Interaction in the (F. Veringa and J Roelofs), 321
Retinula Cells: Polarized Light Responses from Crab (S. R. Shaw), 92
Reversible Oxygen Electrode (J. P Hoare), 703–5
Reykjavik: Meeting on Haemorheology at (Dr. G. W. Scott Blair), 1129
Rh Activity of Erythrocyte Stroma: Sulphydryl Reagents and (F. A. Green), 852
Rhenium: Chemistry of Technetium and (Prof. R D. Peacock), *review* by Prof D C Bradley, 235
Rhizoctonia in a Cultivated and a Fallow Soil in Hong Kong: Incidence of (M. Chu), 862
Rhodium-106 measured with Calculable Overall Accuracy: Half-lives of Barium-137*m*, Silver-109*m* and (V. Middelboe), 283
Rhodopsin Solution: Optical Rotation of Irradiated (Y. Kito and M. Takezaki), 197
Rhynchocephalian from Germany *Elachistosuchus*, a Triassic (Dr. A. D. Walker), 583–5
Rhythmic Activity within Various Thalamic Nuclei Patterns of Spontaneous (Dr. P Andersen et *al*), 888
Ribble Estuary, Lancashire, England Detection of Thorium-234/Protactinium-234*m* in Sediments from the (J. W R Dutton), 1395
Ribonuclease Concentrations in L-Asparaginase-treated Lympho-sarcomata: Change in (Dr L. T. Mashburn and Prof. J. C. Wriston, jun.), 1403
Ribonuclease: Mechanism of Action of Bovine Pancreatic (Dr A. Deavin et *al*), 252–5
Ribonuclease-reactivating Enzyme based on Disulphide Exchange. New Assay of the (P. Venetianer), 643
Ribonuclease from Unfertilized Eggs of the Sea Urchin, *Psammechinus miliaris*: Purification and Characterization of (P. Ferlund and Prof. L. Josefsson), 1402
Ribonucleic Acid: Fractionation of Partially Degraded Tobacco Mosaic Virus (S. Williams and Dr. P. R Whitfeld), 102–4
Precursor–Product Relationship between Nuclear and Cytoplasmic (U N. Singh and R. Koppelman), 75–7
Two-dimensional Thin-layer Chromatography of the Major Mononucleotides of (Dr. J. L. Starr and B Ramberg), 414
X-ray Diffraction Studies of Double Helical (Dr. S. Arnott et *al.*), 227–32
s-Ribonucleic Acid Aggregation induced by Magnesium Ions: Effect of Temperature on (D. B. Millar), 1088
Ribonucleic Acid in a Cell-free System: Polypeptide Synthesis directed by a Bacteriophage (Dr B. F. C. Clark and Dr. K. A. Marcker), 378–80
5S Ribonucleic Acid in Ribosomes from Mammalian Tissues (R. J. Bachvaroff and V Tongur), 248–50
Ribonucleic Acid Synthesis for Deoxyribonucleic Acid Replication in Bacteria Requirement for (Dr. C. O Doudney), 39–41
Ribonucleic Acid Synthesis in Macrophages in Relation to the Secondary Immune Response *in vitro* (Dr. G Harris), 154
Ribonucleic Acid Turnover in Tobacco Leaves infected with Tobacco Mosaic Virus (Dr. P. Babos), 972–4
Ribonucleic Acid in the Young Oocytes of Amphibians: Ultra-structural Transport Mechanism of Messenger (T. Takamoto), 772
Ribonucleic Acids: Cytokinins in (A R. Bellamy), 1093–5
Ribonucleoside into Soluble Proteins: Incorporation of Histamine (Prof. S. G. A Alivisatos et *al*), 187
Ribosomal Aggregation in Lymphocytes: Variability of (Dr H. A. Johnson, H. Schnappauf, A. D. Chanana and Dr. E P Cronkite), 420
Ribosomes from Mammalian Tissues. 5S RNA in (R. J. Bachvaroff and V. Tongur), 248–50
Ribosomes. Polypeptidyl-sRNA and Amino-acyl-sRNA Binding Sites on (M. S. Bretscher and Dr. K. A. Marcker), 380–4

Transition State in the Inversion of the Sachse Hexagon (J. A. Christiansen), 184
Transitions in Hexachloro-co-ordinated Titanium and Chromium: Electronic (C. Dijkgraaf et *al.*), 185
Translocation of Amino-acids in Sugar Beet (K. W. Joy and A. J Antcliff), 210
Translocation Possible Localization of the Genes for the Kidd Blood Group on an Autosome involved in a Reciprocal (M. Hultén *et al.*), 1067
Translunar Radio Communication: Method for (Dr. W. W. Salisbury), 950
Transmission through the Atmosphere at 10 Microns: Effect of Precipitation on (R. W. Wilson and A. A. Penzias), 1081
Transmission from Inhibitory and Excitatory Nerves: Model of the Membrane of Smooth Muscle Cells of the Guinea-pig Taenia Coli Muscle during (M. R. Bennett), 1149–52
Transmissions: Comparisons of Frequency by Long Path Very Low Frequency (V. B. Gerard), 1284
Transplantation: Biology of Tissue (P. S. Russell and A. P. Monaco), *review* by Dr G. Gowland, 685
Transplantation Effects on Canine Plasma Lipids: Liver (W. S Worth et *al.*), 78
Transplantation of a Frog Bladder-fluke from One Host Species to Another: Successful (J. B. Mitchell), 305
Transplantation Resistance induced by Polyoma Tumour Homografts Effect of Thymectomy on (R. C. Ting), 1000
Transplanted Trophoblast in the Golden Hamster Vascular Migration of (Dr. W. D. Billington), 988
Transport of Alkali Ions in a Model System driven by Water Flow (J Rastas, A. Ekman and Dr. S. Salminen), 1152–4
Transport by the Antarctic Bottom Current on the Bermuda Rise: Sediment (Prof. B. C. Heezen *et al.*), 611
Transport Mechanism of Messenger Ribonucleic Acid in the Young Oocytes of Amphibians: Ultrastructural (T. Takamoto), 772
Transport Processes and Thermodynamic Equilibrium (Prof. A. G. McLellan), 359–61
Transportation Networks: Programming, Games and (Prof. C. Berge and Prof. A. Ghouila-Houri), *review* by Dr. H. O. Foulkes, 1125
Trauma and Melanoma Production (Dr. F. N. Ghadially), 1199
Trees of Brunei State: Manual of the Dipterocarp (Dr. P. S. Ashton), *review* by L. L. Forman, 567
Treherne, Dr. J E., and Maldrell, Dr. S. H. P.: A Neural Fat-body Sheath in a Phytophagous Insect (*Carausius morosus*), 215
Trematoda, Aspidobothria: Sense Receptors of *Multicotyle purvisi* Dawes, 1941, (K. Rohde), 820–2
Trematodology: Essentials of (Academician K. I. Skrjabin), Trematodes of Animals and Man, Vol. 18, *review* by Prof. B. Dawes, 1236
Triassic Rhynchocephalian from Germany: *Elachistosuchus*, (Dr. A. D. Walker), 583–5
Tribology for Some, 787
Tricart, J.: Principes et Méthodes de la Géomorphologie, *review* by Prof. T. N. George, 1018
Triggle, D. J., and Moran, J. F.: Rate-determining Step in the Action of L-Amino-acid Oxidase, 307
Triggs, E J., and Beckett, Prof. A. H.: Determination of Nicotine and its Metabolite, Cotinine, in Urine by Gas Chromatography, 1415–7
Trindle, Margaret R., et *al.* Monovalent Cation Requirement for the Aminoacyl Transfer Reaction in Protein Synthesis, 1302
Trinitrophenyl Derivatives: Method for Estimating Free Asparagine and Glutamine in Biological Fluids as (Dr. J. D Broome), 602–4
Triplet: Effect of Deuterium Substitution on Radiation-less Decay of Anthracene (Dr. A. Beckett), 410
Triplet Excitons produced by Ionizing Radiation in Aromatic Materials: Diffusion of (Dr. R. Voltz et *al.*), 405
Triplet–Triplet Annihilation Rate in Anthracene Crystals: Effect of Temperature on the (G. F. Moore), 1170
*Trismonoalkylaminoboranes*in Organic Synthesis: the Exploitation of a New Type of 'Activated Ester' (T. Levitt and Dr. A. Pelter), 299
Tritiated Angiotensin Preparation and Purification (Dr. R. R. Smeby, Dr. P. A. Khairallah and Dr. F. M. Bumpus), 1193
Triticum aestivum: Induced Mutation affecting the Control of Meiotic Chromosome Pairing in (Dr. R. Riley, et *al.*), 368
Tritium in Hydrothermal Solutions: Origin of (S. H. Wilson), 272
Tritium Labelled DNA-Protein in the Mixed Leucocyte Reaction *in vitro*: Efficiency of Scintillation Counting of (Dr. J. F. Moorhead and Dr. W. McFarland), 1157–9
Troll, Prof Walter, et *al.* *In vivo* Complex Formation of Actinomycin *D* and Deoxyribonucleic Acid, 84
Trombiculid Mites (Acarina) from Ground Holes: Recovery of Unengorged Larval (Dr. W D. Kundin et *al.*), 1213
Trophoblast in the Golden Hamster: Vascular Migration of Transplanted (Dr W. D. Billington), 988
Tropical Plant Ecology with Special Reference to West Africa: Forest and Savanna: (Dr. B. Hopkins), *review* by F. N. Hepper, 237
Troup, G J , and Hutton, D. R.: Paramagnetic Resonance Centres in Amethyst and Cystine Quartz. 621
Trout *Salmo trutta* L. of Llyn Padarn, Caernarvonshire: Decline in the Occurrence of *Diphyllobothrium* Plerocercoids in the (A. M. Powell and Dr. J. C. Chubb), 439
Trudgill, Dr. P W., and Widdus, R.: D-Glucarate Catabolism by Pseudomonadaceae and Enterobacteriaceae, 1097–9
Trypsin Inhibition by Phenylmethylsulphonylfluoride with Reduced Wool as Substrate (Dr. P. T. Speakman and R. E. Yarwood), 201
Tryptophan Path Intermediate 1-(o-Carboxyphenylamino)-1-deoxy-D-ribulose 5-Phosphate Chemical Synthesis of the (Dr C. H. Doy), 736
Tsigalidou, Vasilia, Simotas, A. G., and Fasoulas, A.: Chromosomes of the Coypu, 994
Tsuruta, S , and Cameron, A. G. W.: Rotation of Neutron Stars, 356
Tubular Columns in Gas Chromatography: Open (L. S. Ettre), *review* by E. A. Walker, 1022
Tucker, D F., et *al.*: Effect of Thalidomide on the Graft versus Host Reaction, 1308–10
Tulloch, H. J. C., and Young, Dr. D. A.: Synthetic Single Crystals of Graphite, 730
Tumour Cells *in vivo*: Radiation Recovery Response of Mammalian (Dr. J. A. Belli et *al.*), 662
Tumour Homografts: Effect of Thymectomy on Transplantation Resistance induced by Polyoma (R. C. Ting), 1000
Tumour and by Sarcoma S-180 *BALB*. Uptake of Iodine-131-labelled Atabrine by Ehrlich Ascites (Dr. L. J. Anghileri), 878
Tumour recurring after a TCD_{95} Radiation Dose: Response to X-irradiation of a (Dr. H. D. Suit), 956
Tumours: DNA Content of Mitotic Nuclei of Two Mouse (Dr. E. L. Alpen and M. E. Johnston), 715–7
Tumours induced by Rous Sarcoma Virus: Complement-fixing Antibodies in Monkeys bearing (M. J. Casey et *al.*), 1417
Tumours and Sarcomata Induced in Rats by *N*-Hydroxy-2-acetyl-aminofluorene Skin (C. M. Goodall and S. Gasteyer), 1422
Tungsten: Arrangement of Atoms in the First Monolayer of Nickel on (Dr. J. P Jones), 479–81
New Metal-rich Phosphides of Niobium, Tantalum and (Dr. S. Rundqvist), 847
Tungsten, Molybdenum and Titanium: Crystallographic Shear and Diffusion Paths in Certain Higher Oxides of Niobium, (Dr. S. Andersson and Dr. A. D. Wadsley), 581–3
Tunguska Meteor: Anti-matter Content of the (R. V. Gentry), 1071
Tunnel: Submarine Railway: Channel, 335
Tupaia glis: Breast Cancer in a Tree Shrew (O. S. Elliot et *al.*), 1105
Turbulent-flow Properties of Deoxyribonucleic Acid Solutions (Dr. J. W. Hoyt), 170
Turchin, V. F.: Slow Neutrons, *review* by Dr. W. M. Lomer, 18

INDEPENDENCE FOR UNIVERSITIES

NOT very long ago, the University Grants Committee was like Caesar's wife. To universities, it was a sure defence of independence. To British governments, it was a way of spending large sums of money without worrying too much about the details and the responsibility. To visitors to Britain it was, or at least was said to be, a triumph of public administration, a marvellous embodiment of the art of compromise, and the last word in common sense. And certainly there was something remarkable and even admirable about the concept of an institution which could intervene in the financing of universities from public funds in such a way as to prevent the donor from feeling cheated and the beneficiary compromised. But all that was three years ago.

The present mood in the universities is very different. The University Grants Committee no longer seems a comfortable bulwark against interference from outside. Instead, it has taken to asking awkward questions about cost-effectiveness. Sometimes it seems to the universities to be a branch of the Civil Service. Ironically, this transformation has happened since the Robbins Report sketched out what seemed to be a glorious future for the universities. Sir Ifor Evans was right, in his farewell address to the faculty at University College, to single out that document as a turning point (see page 2 of this issue), but the reasons are much more complicated than mere misinterpretation, mischievous or otherwise.

It is sometimes forgotten that the Robbins Report was not merely a charter for the universities but a proposal that there should be a massive expansion in higher education as a whole. Two governments in succession have accepted that as many young people as possible should receive some form of higher education. Increasingly, however, they have found it necessary to make decisions about the allocation of resources among different kinds of institutions—teacher training colleges, technical colleges, regional colleges and universities.

It is perhaps inevitable that the present Government should be tempted, first of all, to spend money where it will be most quickly effective in increasing the amount of higher education. This is one of the reasons why universities have found themselves, in the past two years, ill-equipped to carry out the expansion which the Robbins Report declared necessary. This is also why the University Grants Committee itself has been required to see that the funds available to the universities are spent as efficiently as possible. Even if the University Grants Committee were still a dependant of the Treasury rather than the Department of Education and Science, it could not hope to be immune to pressures in these uncomfortable directions. The scale of the current growth of higher education in Britain makes the isolation of one sector impossible.

The universities have probably increased their own difficulties by complacency since the Robbins Report, which was more concerned to demonstrate the need and feasibility of more higher education than to decide how best to provide it. It was probably sensible to assume, as a first approximation, that a substantially enlarged university system would not be qualitatively different from what there is at present. One consequence, however, was the foolish conclusion that an increase of the university population would require the creation of more small universities. The Government has done right to set its face against this tendency. A few really big universities would be a better investment, academically as well as financially. It would have been better if the universities and not the Government had first made this point.

Another consequence of the Robbins Report was the sanctification of much that is traditional in British academic life. The ratios of staff to students assumed by the Robbins Commission have, for example, become magic numbers, yet the universities would be better able to defend themselves against suspicions of extravagance if they had seriously considered what economies could be won from greater size, or by means of variations of the ratio from one academic discipline to another. And they would be able to put their arguments more effectively if more power resided with the vice-chancellors who must represent them in the outside world.

If there are defects in the position of the universities, however, it does not follow that the Government is blameless. The present shortage of funds, especially for buildings, and the uncertainty about the immediate future, may be a spur to economy but it is also damaging to the health of the universities. At the same time, the consequences of what is called the "second tier" policy have only been loosely thought out. It is right, of course, that the Government should strengthen the technical and regional colleges; grouping them into units called polytechnics should do a lot to help. But is it really wise to create a system in which there will be two sharply contrasting types of institutions for higher education? It is surprising that the Secretary of State for Education and Science has not recognized the beginnings of a problem which is the adult equivalent of the old gulf between the grammar and the secondary modern schools.

How, then, should the universities defend their interests? The first need is to recognize that the protective influence of the University Grants Committee has probably gone for good. A retreat from dependence on public money, which appeals to Sir Ifor Evans, is also impracticable. It follows that there has to be some coherent body which can speak for the universities as a whole. The Committee of Vice-Chancellors is the obvious instrument, but it will have to become much more active if it is to be effective. The ideal is that the universities should collectively determine how they can best satisfy the needs outlined in the Robbins Report and the frequently conflicting needs of the

British economy. The best guarantee of independence would be to take the initiative in solving the problems which exist.

DEAD DUCK INTO PHOENIX

STUDENTS of the Ministry of Technology, enemies as well as friends, must now acknowledge that a change for the better has overtaken that agency of the British Government originally created to foster change elsewhere. One sign of what is happening was the speech which the Minister of Technology, Mr. Frank Cousins, made to the Confederation of Shipbuilding and Engineering Unions on June 22. Almost for the first time there were traces of what could well become, with diligence and persistence, a coherent strategy to replace the rudderless philosophy of the past two years. What seems to have happened is that the Ministry has recognized how much of its work must be dull and unspectacular. In some fields, such as computers and electronics, it will have to lavish special care and attention until somebody finds a solution to the problem of how comparatively small societies can remain in the forefront of technological change without losing money. But the potential benefits of steadily increasing efficiency in less-spectacular industries are just as great, and this is the lesson that is sinking home. It is especially welcome that, in his speech at Torquay, Mr. Cousins should have gone out of his way to emphasize the promise of a link between increasing efficiency and increasing prosperity, for technology is not an end in itself but a means of living better.

Some of the tangible benefits of the new realism at the Ministry of Technology are the National Computer Centre soon to be started at Manchester, and the solid work on industrial standardization now under way. There have also been a number of recent development contracts which are at once imaginative and down-to-earth. The programme to develop methods of computer control for chemical plants is a good example, and of course it is entirely sensible that the Ministry should now try to make good use of the regional offices which the old Department of Scientific and Industrial Research established in the hope of helping industry to greater efficiency. Unfortunately, however, sweet reason is not everywhere apparent. The Ministry's chronic trouble has been the pretence that it could fly before it could walk. Traces of this old Adam are still there. Mr. Cousins, for example, was talking of the "Breakthrough Programme" that would be built around the laboratories of the old Ministry of Aviation as if he still thought office had put a magic wand into his hand. There is still a danger that the Industrial Reconstruction Corporation, which gives the Board of Trade powers to buy into private industries, will go to Technology's head. And the Ministry has not yet begun to tackle some of the great and outstanding problems such as industrial retraining. It is too soon for watchdogs to look elsewhere.

NEWS AND VIEWS

Plain Words

SIR IFOR EVANS, the retiring Provost of University College, London, put into words some of the current discontents of British universities in his address to the Assembly of Faculties on June 23. In particular, he lamented "the complete surrender of the universities to government finance and in so many insidious ways to government control. It has, of course, all grown worse since the Robbins Report . . ." But the trouble, Sir Ifor said, was not to be found in the report itself, but in the way in which it had been interpreted. By implication, the Robbins Report had become a licence for interference.

For much of his fifteen years as Provost, Sir Ifor has evidently been captivated by a vision of independence for University College, and this has plainly become more attractive as the forces of expansion and inflation have made independence steadily less attainable. At current prices, Sir Ifor estimated, it would cost £80 million to buy complete autonomy, and, though he is evidently hoping that a benefactor of such generosity may somewhere exist, most of those who heard him speak considered such a sum of money a sufficient proof of the necessity of the University Grants Committee.

Even so, Sir Ifor had a pointed tale of how in 1931 the College had to sell, for lack of £35,000, a piece of land which it is now having to acquire again for more than £1,000,000. He complained that the University Grants Committee in the fifties backed the founding of the University of Sussex because congestion on the sites of the London colleges meant that the "development in that area of a university institution is a particularly difficult and expensive operation". This restriction has now been eased, if not entirely dispelled, and Sir Ifor seems to have persuaded the present chairman of the University Grants Committee that the College should be allowed to expand outside its traditional rectangular plot, and that it should be allowed to pay market prices as well. He has had less luck on student housing, and confessed himself "astounded" that the University Grants Committee says that "not a pound of their money" should go on hostels. But he feels most strongly of all about interference from outside, and about "the imposition of regulations and memoranda that may ultimately turn the best creative and scientific minds in this country into mere university administrators, keeping their departments tidy for Government inspection, or the next round of reform". For his part, Sir Ifor said, he would have preferred to live in the "age of Rutherford than in the age of Franks". Because he is known to be a traditionalist, some of what Sir Ifor said may be discounted, but his break with the tradition of public gentility for the heads of universities could itself be an important move in the imminent tussle about the financing of the next university quinquennium.

No Pause in France

FRENCH science appears to be deliciously immune from the talk of deceleration of the growth of expenditure to be heard in the United States and the United Kingdom. The Fifth Plan makes it plain that expen-

diture on scientific research and development in France is intended to grow steadily, absolutely and as a proportion of the Gross National Product, until it amounts to 2·5 per cent of the wealth of France by 1970. In a comment on these plans prepared by the French Embassy in London, it is made quite plain that "France's financial outlay must be determined by reference to that of neighbouring countries". From this point of view, the argument goes, the target of 2·5 per cent is, if anything, a minimum. (The current British rate of expenditure works out at something between 2·5 per cent and 2·7 per cent according to the basis for calculating the GNP.) The pace of the proposed French development is measured by the fact that, in 1962, scientific research and development accounted for a mere 1·8 per cent of the GNP. Another yardstick is that the numbers of people employed on scientific work and in higher education in France are expected to double between 1963 and 1970, which in turn requires an increase of the annual output of trained scientists and engineers from French universities from 10,000 in 1963 to 21,000 in 1970.

So far as science is concerned, the Fifth Plan is uncommonly explicit about the way in which effort shall be distributed among the various fields of expenditure, largely on the strength of survey of possible developments carried out by the Research Commission. Most of the development in prospect is concentrated in the physical sciences, as shown by the following table of the allocations to capital expenditure from public funds :

	Expenditure (millions of francs)
Mathematics	315
Physics	1,254
Chemistry	400
Earth sciences	284
Oceanography	150
Biology and medicine	590
Agriculture	390
Building, planning	162
Human sciences	120
Patent rights	10
Inter-disciplinary operations	225
Space	2,000
Total	5,900

France will gain from this expenditure an impressive range of establishments and institutes. The way in which it has been decided that certain universities and university departments should be singled out for rapid growth in a particular field is also an echo of the "centres of excellence" doctrine of the United States, and possibly an example to other European countries in this respect. But other countries, of course, will envy most of all the buoyant growth planned for the next five years.

Next Leap Forward

THE proposal that a 300-GeV proton accelerator should be built somewhere in Europe and within the organization of CERN moved a little nearer reality in June with the thirty-second meeting of the Council of CERN at Geneva. It will be a long time yet before European governments are required finally to say whether they will contribute to this project, and how much. Nevertheless, by the end of this year it should be plain which are the favourites among the twelve sites from nine countries now being studied in considerable detail. Given the great cost of the 300-GeV machine and the fact that its siting will employ a nearby work force of between 10,000 and 15,000 men and their families, it is unlikely that the interested countries will be able to separate from each other decisions on where the accelerator should be built and how its cost should be apportioned.

Enthusiasm for the machine, however, remains as great as ever. The European Committee for Future Accelerators, meeting during May, reaffirmed its belief in the Amaldi Report (1963) which first seriously recommended the 300-GeV machine and which argued for a great expansion of comparatively smaller accelerators as well. In the three years since the proposal for the accelerator first became tangible enough to feature in diplomatic discussions, there has already been a considerable growth of interest in less ambitious machines. The Committee for Future Accelerators was pleased, in May, to see how plans are being advanced for a meson factory at Zurich, a 2·5-GeV electron accelerator at Bonn, and the electron-storage rings intended to work with the accelerator at Frascati, near Rome. But the "summit programme", as it is called, remains the Committee's chief objective. It has also declined to budge from the view that what a country spends on high-energy nuclear physics within the structure of CERN should be balanced by at least an equal amount of expenditure in national centres and universities. The passage of time may well ensure that this hope is fulfilled, for there are those who think that each month sees a strengthening of the centrifugal tendencies which tempt individual countries, from time to time, to think it would be better to have a machine of their own, smaller though it would have to be.

Migraine Research

A NATIONAL appeal to help the "millions of migraine sufferers" has been launched by Lord Brain for the Migraine Trust, which is trying to raise £750,000 to finance a research programme. In particular, it wishes to establish a hospital in-patient unit of 16 beds, at a cost of £370,000, so that full metabolic and radiological studies can be carried out on patients during and after attacks. Research is already being carried out at the Migraine Clinic in the National Hospital, London, but this needs £30,000 to speed and to expand its work on the variation and associated change in the size of blood vessels in certain parts of the brain during an attack, and on the connexion of migraines with abstinence from food.

Describing a survey into the incidence of migraine which has been started in the Rhondda Valley with support from the Medical Research Council, Lord Brain said, "As soon as possible we plan to develop the survey into a detailed population study, taking into account other branches of medical research, and covering a period of three years". To allow for regional variations, a survey in Scotland under the auspices of the University of Glasgow is being planned.

The most important work of the Trust is to co-ordinate and assess similar research in medical centres throughout the world. Lord Brain stated that in addition to co-ordinating work in Britain the Migraine

Trust plans to publish a quarterly journal which will carry abstracts from important world-wide literature as well as original papers on migraine. A symposium is planned for this autumn and the first international symposium will be held the following year.

Project for Engineers

THE Department of Education and Science launched a new magazine this week in its continuing attempt to interest senior school students in engineering as a career. *Project* will be published three times a year and 24,000 copies will be distributed to fifth and sixth forms throughout Britain. The engineering institutions are anxious to see the magazine succeed and are contributing articles and information but not money. The aim is to give a favourable impression of various types of engineering, the training required to become a qualified engineer, and the example of well-known engineering innovators—this first issue includes a profile of Dr. Barnes Wallis of the British Aircraft Corporation, whose ideas have not always been immediately accepted by the British Government but whose inventiveness and originality, according to the editor of *Project*, make him one of the outstanding engineers in Britain.

The magazine, a £10,000 glossy product, is produced by the Central Office of Information for what is known as the Publicity Working Party on Engineering Technology—the custodian of the British Government's hope that more students will be attracted into engineering and technology. Other projects have included a travelling exhibit for schools entitled "Technology Today", which has visited forty-five centres in the past 7 months, and an earlier publication, *Engineering: a Creative Career*, which attempts to present a broad spectrum of engineering problems, the routes to qualification beginning at both 'O' and 'A' levels, and typical university syllabuses. A national exhibition "Engineer's Day" will be held in London in the autumn. Although the new magazine is aimed for students, anyone interested can obtain copies from the Government bookshop or his newsagent at an annual cost of 15*s*.

Safety Cars

THE Road Research Laboratory of the Ministry of Transport has made a tentative bid to do for Britain what Mr. Ralph Nader seems to be doing for the United States. In its most recent report on *Safety Cars* (obtainable either from the Laboratory or the Ministry of Transport), Mr. G. Grime has applied Newton's Second Law to collisions between cars, and has been able to infer a great deal about the relative motion of cars and passengers in the fraction of a tenth of a second which seems usually to be required to crush the front of a car involved in a head-on collision by 60 cm or so. His general conclusion is that seat-belts are among the best means of protection, so that it is no surprise that Mrs. Barbara Castle, the Minister of Transport, should have announced a regulation that will in future require that cars should be equipped with anchorage points for seat-belts.

One of the simplest of Mr. Grime's conclusions is that passengers tend to come into contact with the vehicles which carry them only when the collision is almost at an end. In one calculation, for example, he found that by the time a human body had shot forward by 41 cm from the front seat to strike the instrument panel of a medium car in a head-on collision at 50 km per hour, the crushing of the front of the car would have only 0·5 cm to go. This means that the unlucky passenger would strike an essentially static object, and even the best padding on the instrument panel would entail a deceleration of 64 *g*. A suitably padded and flexible steering-wheel might reduce the deceleration in these circumstances to 35 *g*, but a seat-belt capable of a modicum of stretch could ensure that deceleration amounts to 17·1 *g* in similar circumstances, and that the attendant forces are "applied in a controlled manner over a large and predetermined area". In all this the principle is that a person should be partially anchored to the car in which he rides, so that he can expect to benefit from the energy expenditure involved in crushing the front of the car.

Mr. Grime is not optimistic about the prospects of greater safety by designing the front of a motor-car so as to minimize the consequences of collision. According to the calculations, seat-belts are always better. Mr. Grime does, however, conclude from American experience with would-be astronauts that it would be feasible to design seat-belts capable of decelerating people by something like 30 *g*, compared with the 20 *g* which is now common. His dynamical calculations also persuaded him that there would be advantages in a design for a seat-belt capable of applying a greater force at the limit of its extension, and that the ideal is a situation in which seat-belt and seat are built as an integral whole. Finally, for those who will not wear seat-belts, there are some benefits to be won from crushable fittings on the instrument panel of a motor-car, especially if they can be so arranged as to help decelerating a passenger soon after the beginning of a collision.

Put Out More Books

WHEN Blackwells first opened their doors and started selling books in Oxford, there was room in the shop for only three customers at a time. When their new extension was opened by Sir William Haley on June 16, three hundred guests browsed in traditional Blackwell fashion among the shelves, uncrowded and undisturbed. The new extension was christened the Norrington Room, after the president of Trinity College, under whose quadrangle Blackwells have found room to expand by digging a subterranean bookroom of enormous size.

Despite its size, and the need for artificial lighting, the room is prevented from seeming oppressive by the use of four different floor levels, and a variety of ceiling materials. There is shelving to carry 160,000 books, arranged to make the best use of space, and to break up the room into units of more human size. The expansion will enable Blackwells to carry even greater stocks on the premises, which is important in a service industry where orders must be dispatched as soon as possible. Although the personal shopper represents less than 10 per cent of the turnover, the increase in stock will also be a great convenience to him, particularly in science and technology, where the expansion is concentrated. A quick check in familiar fields confirmed that the increase in stock is quite genuine, which is good news for scientists both in Oxford and elsewhere.

Parliament in Britain

In a written answer to a question from Mr. Boston on June 20, the Parliamentary Secretary to the Ministry of Public Building and Works, Mr. J. Boyden, stated that on the basis of a special enquiry made in 1964 it was estimated that in that year the construction industry spent about £2·5 millions on research. This is the equivalent of 0·3 per cent of its gross output, compared with a national average for all industries of almost 2·7 per cent.

In opening an adjournment debate on building methods and bad-weather precautions on June 21, Mr. Boston returned to the question of the attitude of the building industry to research, and Mr. Boyden, replying for the Government, said that the Minister, Mr. R. Prentice, had that day held a conference with those concerned with setting up a new organization for research and information in the construction industry. The discussions had gone well, and many sections of the industry were sharing a keen interest in raising the necessary funds. The question of continuous working during bad weather and the winter would be an important part of both research and information work. He hoped that the new body would follow up the steps already taken by the Ministry and that in future it would be customary for the industry to work a normal week, except perhaps during cataclysmic weather The need of research was fairly well known and, while agreeing that the construction industry as a whole spent less on research than many manufacturing industries, Mr. Boyden hoped that the new organization would give just the impetus needed.

In reply to a question in the House of Lords on June 21, the Parliamentary Under-Secretary of State for Commonwealth Relations and for the Colonies, Lord Beswick, said that a National Reports Centre had been set up at the National Lending Library for Science and Technology as a British counterpart to the United States Clearing House which produced a fortnightly list entitled *United States Government Research Reports*. The British Centre published a monthly bulletin entitled *British Research and Development Reports* in which accessions to the stock of reports were announced. The service started only this year, and Lord Beswick agreed with the Earl of Bessborough about the importance of distributing the bulletin widely. Any organization could be put on the mailing list if it applied to the National Lending Library.

In a written answer in the House of Commons on June 20, the Minister for Land and Natural Resources, Mr. F. Willey, said that a hydrographic survey of the Wash area, with gravity coring of the sea-bed, current gauging and seismic investigations with tests of samples, would form an integral part of a feasibility study of a Wash barrage. It would be wrong, Mr. Willey said, to embark on such a scheme except as part of a comprehensive investigation. The report on the Water Resources of the Great Ouse Basin suggested a five-year programme of investigations which, with the preparations of designs and estimates, would cost about £1·5 million. The hydrographic survey and related soil investigations, including boreholes, would account for almost £1 million and would take two to three years.

University News:

Aberdeen

Mr. D. F. Kerridge has been appointed to the chair of statistics as from August 1.

Aston

Mr. A. J. Ede has been appointed professor of mechanical engineering as from August 1.

Leeds

Dr. D. Dowson has been appointed to the chair of fluid mechanics and tribology in the Department of Mechanical Engineering.

London

Dr. G. S. Nelson, reader in medical parasitology in the London School of Hygiene and Tropical Medicine, has been appointed to the William Julien Courtauld chair of helminthology tenable at that school.

Manchester

Mr. C. R. Illingworth has been appointed to a newly established additional chair of mathematics; Dr. F. D. Kahn has been appointed to a newly established second chair of astronomy; Dr. D. B. G. Edwards has been appointed to a newly established chair of computer engineering.

Announcements

Mr. Nigel Calder, editor of the *New Scientist* since 1963, will be leaving his present post on October 1 this year. He will be succeeded by Mr. Donald Gould, who has won a considerable reputation in recent years, chiefly as a free-lance writer on medical subjects. Mr. Calder intends to devote himself to free-lance writing.

Over 300 British scientists have signed an appeal to the French Government to cancel the new series of nuclear tests about to be made in the Pacific. The protest was published this week as a full-page advertisement in the Paris weekly *Le Nouvel Observateur*. Over 30 of the signatories are Fellows of the Royal Society or heads of departments at British universities.

Dr. Columbus O'Donnell Iselin has been awarded the fourth Henry Bryant Bigelow Medal for Oceanography by the Woods Hole Oceanographic Institution. Dr. Iselin is a former director of the Institution and has held the Henry Bryant Bigelow chair there since 1958; he is also professor of oceanography at Harvard University and the Massachusetts Institute of Technology. Dr. Bigelow was the first director of Woods Hole, holding the post from 1930 until 1940, and was also the first recipient of the Medal, which was awarded him in 1961.

Prof. T. Bergeron has been awarded the International Meteorological Organization Prize by the Executive Committee of the World Meteorological Organization. This Prize is awarded annually for outstanding work in meteorology and international collaboration.

Dr. Paul-A. Giguère, director of the Department of Chemistry in the Université Laval in Quebec, has been elected president of the Chemical Institute of Canada during 1966–67.

The following have been elected honorary fellows of the Institute of Biology: Sir Macfarlane Burnet, Prof. E. B. Chain, Dr. J. C. Kendrew, Sir Peter Medawar.

Dr. E. A. Walker, president of the Pennsylvania State University and chairman of the National Science Board, has been elected president of the U.S. National Academy of Engineering, in succession to Dr. A. B. Kinzel.

AT its annual general meeting, the Association of Applied Biologists elected the following honorary officers for 1966–67: *President*, Sir Vincent Wigglesworth; *Vice-President*, F. Raw; *President-Elect*, D. J. Watson; *General Secretary*, F. T. Last.

THE first volume of the newly launched *British Film Guide* lists some 1,700 films directly or indirectly related to medicine. The intention is that the completed *Guide* will list by subject all non-fiction films available in Great Britain. It will appear in twelve volumes, the first of which can be had from Film Centre (International), Ltd., 24 Conduit Street, London, W.1, price 39*s*. 6*d*.

ARRANGEMENTS have been made for the Russian journal *Genetika*, first published in Russia in 1965, to be translated into English on a continuing basis. Further information concerning this journal can be obtained from Clearinghouse for Federal Scientific and Technical Information, Joint Publications Research Service, Tempo E., 6th and Adams Drive, S.W. Washington, D.C. 20442.

THE next joint meeting of the Challenger Society and representatives from the Marine Laboratories will be held in the University of Southampton during July 21–22. Further information can be obtained from N. J. Holmes, Department of Oceanography, University of Southampton, Southampton.

THE third annual meeting of the Society for Cryobiology will be held in Boston during August 8–10. Further information can be obtained from Dr. C. Huggins, Department of Surgery, Massachusetts General Hospital, Boston.

THE second international congress of food science and technology will be held in Warsaw during August 22–27. Further information can be obtained from Dr. A. Borys, Instytut Przemyslu Miosnego, Warsaw 12, Rakowiecka 36.

A SYMPOSIUM on "Solar-Terrestrial Physics" will be held in Belgrade during August 29–September 2. Further information can be obtained from Dr. D. Bajic, URSI Belgrade Symposium Committee, P.O. Box 356, Belgrade.

THE eleventh international symposium on "Combustion" will be held in the University of California, Berkeley, during August 14–20. Further information can be obtained from the Combustion Institute, 986 Union Trust Building, Pittsburgh, Pennsylvania.

THE sixth international congress for electron microscopy will be held in Kyoto during August 28–September 4. Further information can be obtained from the Chairman of the Organizing Committee of the Congress, Institute for Virus Research, Kyoto University, Kyoto.

THE tenth international conference on "Low Temperature Physics" will be held in Moscow during August 31–September 6. Further information can be obtained from the Organizing Committee of the Conference, Institute for Physical Problems of the Academy of Sciences of the U.S.S.R., Vorobyevskoye Shosse 2, Moscow B-334.

A SYMPOSIUM on "Neutron Monitoring for Radiological Protection", under the auspices of the International Atomic Energy Agency, will be held in Vienna during August 29–September 2. Further information can be obtained from S. Somasundaram, Division of Health, Safety and Waste Disposal, International Atomic Energy Agency, Vienna.

A SYMPOSIUM on "Collection and Processing of Field Data", under the auspices of the Commonwealth Scientific and Industrial Research Organization, will be held in Canberra during August 30–September 2. Further information can be obtained from Dr. E. F. Bradley, Division of Plant Industry, P.O. Box 109, Canberra City, A.C.T.

THE fourth international Biometeorological Congress will be held at Rutgers University during August 26–September 2. There will be two plenary sessions on "Biometeorological Properties of the Atmospheric Environment" and "Impact of the Atmospheric Environment on the Integument of the Organism". Further information can be obtained from F. Sargent, 524 Burrill Hall, University of Illinois, Urbana.

A MEDICAL congress on the theme "Clinical Physiology and Internal Medicine", organized by the Czechoslovak Society of Internal Medicine, will be held in Prague during August 29–September 2. The congress will include a symposium on "Conception and Methods of Clinical Physiology". Further information can be obtained from the Congress Office, Fourth Medical Clinic Faculty of General Medicine, Charles University, U nemocnice 2, Prague 2.

A SYMPOSIUM on "Origin and Distribution of the Elements", organized by the International Association of Geochemistry and Cosmochemistry and co-sponsored by the United Nations Educational, Scientific and Cultural Organization and the International Union of Geological Sciences, will be held at the headquarters of the Organization in Paris during September 21–23. The symposium will be divided into five sections: theories of origin; solar, stellar and interstellar abundances; meteorites; planets, asteroids, comets and tektites; terrestrial abundances. Further information can be obtained from Prof. E. Ingerson, Department of Geology, University of Texas, Austin.

Appointments

THE Minister of Health, Mr. Kenneth Robinson, has appointed Dr. D. Dooley to be H.M. Inspector of Anatomy in England and Wales in succession to Dr. C. G. Nicol, who has retired. The post was established by an Act of Parliament in 1832; the duties involve issuing licences to teachers of anatomy and operative surgery and supervising the curriculum and teaching of these subjects in the medical schools and schools of anatomy in England and Wales.

WHEN Dr. L. Harrison Matthews retires from the Zoological Society of London this week, his work as scientific director will be divided into two new posts. Mr. L. G. Goodwin, director of the Nuffield Institute of Comparative Medicine, will be in charge of research as the director of science. Mr. C. G. C. Rawlins will be director of zoos with responsibility for managing both Regent's Park and Whipsnade zoos. Mr. Rawlins retired this year from the Overseas Civil Service after serving as a district commissioner and gaining considerable experience in administering fauna conservation and game areas. Dr. H. G. Vevers, now curator of the aquarium and invertebrates and assistant to Dr. Matthews, will be the assistant director of science.

MR. I. L. BAUMGART has been appointed assistant director-general of the New Zealand Department of Scientific and Industrial Research on the retirement of Mr. L. W. Tiller. Dr. A. T. Johns has been appointed assistant director-general of the Department of Agriculture, and Dr. G. Butler will replace Dr. Johns as director of the Plant Chemistry Division of the D.S.I.R.

DR. M. KENT WILSON, professor and chairman of the Department of Chemistry in Tufts University, has been appointed head of the Chemistry Section, Division of Mathematical and Physical Sciences, in the National Science Foundation as from July 1.

DR. J. F. CLARK has been appointed director of the Goddard Space Flight Center, Greenbelt, Maryland, where he has been acting director for a year.

NEW CURRICULA FOR SCHOOLS

WHAT should students be taught at school? For a long time this was a question that needed no answer. The practice of the schools was a sufficient guide to what their practice should be. The construction of the curriculum and its evaluation have for a long time been thought of as slowly changing entities the momentum of which carries them along. This is why it is remarkable that in the past decade or so there has been a rapid growth of interest and experiment designed deliberately to change the curriculum of the schools. Though experiments have been carried out in studies of all kinds—in modern languages and English, for example—the developments there have been in the deliberate design of science curricula stand out for their vigour, their adventurousness and their wide applicability in the schools.

The beginning of this movement is marked by the work of the Physical Sciences Study Committee (PSSC) which grew up at Massachusetts Institute of Technology in the years from 1957 on, and after a number of authorities in the United States had been alarmed by what seemed to be the neglect of science teaching in American high schools. In the United States the initiative in physics was quickly followed by similar developments in other fields—in chemistry and biology, for example. Funds were provided in rapidly growing amounts by the National Science Foundation and by other bodies concerned with the development of the curriculum—school systems, universities and even publishers.

In parallel with these developments in the United States have been similar experiments elsewhere. In Britain, the groups of teachers working within what used to be the Science Masters Association (now known as the Association for Science Education) embarked on a number of developments in the 'fifties. Working largely through voluntary committees, the schoolmasters were able to suggest ways in which more modern topics might be introduced in the school curriculum, and ways in which the style of teaching in science could be designed more adequately to excite the interest and the curiosity of children. At the end of 1961 this voluntary work was in part superseded by the creation of the Nuffield Foundation Science Teaching Project, which brought together a number of different interests in the evolution of the curriculum—the interests of the professional institutions such as the Institute of Physics, for example, and the interests of Scottish teachers and education authorities. The first part of the work of the Science Teaching Project has been published this week, and during the rest of the summer the books which embody O-level courses in physics, chemistry and biology will appear. It is hoped that some hundreds of schools will embark on these new courses in the autumn.

Elsewhere there have been similar tendencies. The book review which appears on page 13 of this issue refers to the work of a curriculum development project in Australia which appears already to have had an important influence on the pattern of science teaching in secondary schools. In Europe a great many countries other than the United Kingdom have undertaken curriculum development for their secondary schools. It is true, of course, that in several countries the pace at which change can occur is limited by the way in which curriculum may often have statutory validity as it does, for example, in Spain and Italy. The movement towards the reform of the science curriculum is not confined to industrial countries, and indeed the under-developed countries of Africa and south-east Asia are as keenly interested in what the new curricula may provide as are the nations with older-established educational systems. For this reason organizations such as PSSC have inspired curriculum developments overseas, particularly in Africa, with support from the Ford Foundation and under the label of Educational Services Incorporated. British interests in this field are likely to be channelled into help for less-developed countries through the newly formed organization called Centre for Curriculum Renewal and Educational Development Overseas which has been sponsored jointly by the Ministry of Overseas Development and the Nuffield Foundation, as well as through a number of older-established institutions, among whom the commercial publishers cannot be neglected.

The fact that such a diversity of curriculum developments has coincided in time is a measure of the way in which the educational systems of industrialized nations have been forced to tackle a number of basic problems of organization. In Britain, for example, the most sustained pressure on the schools in the past fifty years has been the steady growth of the secondary school population. This has meant an increasing diversity of ability and interest at all levels of the school system. It has also meant that the teachers could not count on the willingness of their pupils to grapple with the learning process without prompting. Instead they have had to become increasingly concerned with how best to help children learn and how best to give them the will to do so. In modern languages this has led to the growth of systems of teaching in which children are practically involved in speaking a foreign language from the beginning. In science the tendency has been similar. All the experiments in curriculum renewal now going on have as their common component a wish to give pupils first-hand experience of the process of science. In other words, didactic teaching is being replaced by what is intended to be a regimen of experimental discovery by the pupils themselves. In mathematics, the curriculum development projects, some modest and some ambitious in their intellectual content, also have in common an attempt to give children a feeling for the conceptual structure of mathematics without exercising them in the often dull routines of the subject.

The opportunities and the difficulties which attend the whole process of curriculum development are admirably exemplified by the experience and the ambitions of the Nuffield Science Teaching Project. Here, as elsewhere, the objective has been to devise programmes for teaching science in which experiments by children play an integral part. The argument is that only by such means can children be expected to acquire a deep understanding of physics, chemistry or biology. For one thing, of course, real science is largely an empirical study. For another, doing something with the hands is in practice a vivid way of learning that something. It is also an enjoyable activity, and the devisers of the Nuffield courses have sought deliberately to exploit enthusiasm first captured in a laboratory experiment.

The new science course must also seem like science to the children who will follow it. This means that it is hard to omit all mention of parts of a subject which children know about from their reading of newspapers and books—electrons, for example, or nucleic acids. At the same time, the problems of teaching children about such things without being trapped into didactic talk at the blackboard are substantial. This is why a great deal of effort in the design of new curricula has been put into the design of equipment that can somehow bring large parts of modern science into the school classroom.

But devising a new curriculum is more than just writing a text-book and a set of instructions for teachers.

In reality, it is not possible to predict with anything like certainty the chances that a curriculum devised at the desk will suit the classroom. For this reason the Nuffield courses, like the new mathematics courses of the School Mathematics Project, and like the courses which have been evolved by the American curriculum development projects, are the result of close interaction between the classroom and the developers. The Nuffield courses now being published have been tested in 170 secondary schools over a period of three years. The thoroughness of such feasibility testing is certain in future to be the measure of the quality of a new curriculum.

With a new curriculum must go new styles of examination. If the object is somehow to deepen children's understanding of science, such examinations as there may be must also test understanding if they are to be meaningful. Given the importance of examinations in school systems such as that of Britain, teachers inevitably look to curriculum developers for an initiative in the design of examinations. It may not be the coincidence it seems that the examinations authorities in Britain were prepared to welcome the new style of examination at the time when curriculum development itself became fashionable, for the same pressures are at work throughout the school system. The Nuffield courses have been accompanied by specially designed examinations provided by the examinations boards during the trial period. The examination questions frequently provide the information that would constitute the answer to a more conventional question. Their style is almost certain to influence examinations in school science which are quite unconnected with the Nuffield development.

The design of the curriculum is, as it happens, less difficult than its dissemination in the schools. The pioneering work tends to be done by enthusiasts who are, almost to a man or woman, among the more able teachers. Although well-run feasibility trials must involve teachers of various kinds and schools with varying facilities, it is nevertheless a curious problem in techniques of propaganda to know how best to communicate the intentions of the curriculum developments to those who must in the end make use of the work that has been done. This is why most of the schemes for curriculum development have concentrated on providing materials for use by teachers. By comparison, books for pupils, while not unimportant, take second place. Even so, there are evident and serious limits to what can be done by the sale of books. Teachers the world over are too busy to be able to change their style simply by thinking. It follows that teachers must somehow be given opportunities to inform themselves about new methods of teaching and about new advances in the subject they aim to teach. In the United States a vigorous programme of in-service training, financed largely by the National Science Foundation, has made it possible to introduce some tens of thousands of teachers to the new curricula which have been developed in the past decade. Summer institutes are held at universities throughout the United States and teachers attend them for periods of six weeks or so, often with the benefit of a modest payment for foregoing their normal holiday. In the United Kingdom, circumstances are different; for example, summer holidays are not as long. Even so, the provision of opportunities for teachers to keep up to date in method and content is still far from satisfactory, although in recent months there have been welcome signs of improvement. In the summer this year, for example, British local authorities have arranged upwards of one hundred courses for as many as one hundred teachers at a time to introduce some of the Nuffield materials to some of those who may later make use of them. This will have to be a continuing activity, whether or not the Nuffield courses themselves win general acclaim.

The ideal is a state of affairs in which the involvement of the teachers in the evolution of the curriculum is taken as a matter of course. Just as the involvement of children in practical laboratory work is the best way of helping them to learn science, so the involvement of teachers in the evolution of the curriculum is the best way to give them a feeling for its practicability and educational virtue. The difficulty, of course, is that most teachers are too busy to be concerned with anything but tomorrow's classes. The remedy is that they should be given the time to work on curriculum development either in their own schools, or in groups of teachers recruited locally, or by relying on institutes. So far, permanent arrangements along these lines have not been made in the United Kingdom, although there are now a number of interesting developments involving the creation of science centres for teachers in schools. In some places, local authorities have taken the initiative. Elsewhere the arrival of a new curriculum has first created the need to convey information to teachers and has then suggested the profit there can be in a regular interchange of ideas and suggestions among groups of teachers. It would seem that professional and learned societies have a valuable part to play in furthering arrangements of this kind. In Britain the Institute of Physics is already engaged on a scheme intended to create a close link between a university (Manchester University Institute of Science and Technology) and a large group of physics teachers in the region. This, however, is only a beginning, and it is claimed that there is an urgent need for further experiments in the design of machinery whereby teachers may become caught up in the process of curriculum development, and in which university and professional scientists can more easily and convincingly help in this same process.

The other obvious and continuing need is that of money. So far, in Britain the lion's share of money for curriculum development has been provided by the Nuffield Foundation. Altogether £1 million has been committed to the schemes so far begun. By comparison with investment in the United States, for example, this is a tiny sum, especially because of the range of the projects now being carried through. There are, for example, a scheme for dealing with primary school science, schemes to carry the science courses for children between eleven and sixteen through into the sixth form, and schemes intended to cater for children of varied ability, and for schools wishing to teach science as a single subject and not several. In the long run the obvious source of finance for continuing work of this kind is the Schools Council, recently formed and jointly financed by the local authorities in Britain. Individual authorities themselves, and the publishers as well, have a further part to play. But in a sense the greatest danger may be that the current wave of curriculum development may be regarded by those who hold the purse-strings as a once-and-for-all endeavour, complete in itself.

In reality the last thing that any school system needs is a static curriculum. The ideal is a dynamic process of change in which the content of what is taught as science, and the way in which it is taught, are sensitively matched to the needs of pupils in schools, the ability of their teachers, and the demands of the society in which they live. This implies that the success of a new curriculum should not be judged by the degree to which it is accepted in its entirety by teachers, but rather by the degree to which it fires the enthusiasm for change of all concerned with education. In practice, this means that those who launch new curricula must particularly value those teachers who look critically at a new course and decide that some parts of it can be successfully taught, and that some parts of it should—in the circumstances of a particular school—be left aside. For these are the teachers whose criticism may eventually mature into individual contributions to a still better course of study. In other words, each new curriculum is only a stepping-stone to a better one.

BIOGENESIS OF MITOCHONDRIA*

By DR. D. HALDAR†, DR. K. FREEMAN‡ and DR. T. S. WORK
National Institute for Medical Research, Mill Hill, London, N.W.7

"MITOCHONDRIA can be seen to swell, coil, branch, fragment, coalesce, put out pseudopods, even to get tied in knots. They can change their form until they resemble bubbles, strings of beads, dumb-bells, lemons or snow-shoes" (Ritchie and Hazeltine, 1953). Despite this variability in form, mitochondria from yeasts, fungi, plants and animals resemble one another in both enzyme content and function. They contain traces of deoxy-ribonucleic acid (DNA)[1], significant quantities of ribo-nucleic acid (RNA)[2] and large quantities of phospholipid and protein. Much of the protein is, moreover, unique to the mitochondrion and does not occur elsewhere in the cell. We now accept that the DNA of the nuclear genes codes for formation of several different types of RNA and that one of these, messenger RNA, in turn codes for the amino-acid sequence of proteins formed on the cytoplasmic ribosomes. Where then are the mito-chondrial proteins synthesized; are they formed on the ribosomes and transferred to the mitochondria to be self-assembled therein, or are they formed by some in-dependent system within the mitochondria? Isolated mitochondria, suspended in buffered succinate, will un-doubtedly incorporate radioactive amino-acids into proteins over long periods[3]; nevertheless, malic dehydro-genase and cytochrome *c* (typical mitochondrial proteins) when extracted from these labelled mitochondria are themselves completely devoid of any radioactivity[4]. This paradox presents something of a challenge and has occupied much of our attention.

Although much of the progress made in the understand-ing of mechanisms of protein synthesis has been achieved by the use of cell-free systems, the very existence of this paradox indicated that it might be advisable to return for its resolution to the study of whole cells. When "Krebs" ascites tumour cells§ are incubated in a suitable nutrient medium there is rapid protein synthesis. At 37° C the rate of synthesis is too rapid to permit successful pulse labelling experiments, but if the temperature is lowered to 22° C protein synthesis is slowed down sufficiently so that a 'chase' of cold amino-acid added to the medium stops (almost instantly) the incorporation of a radioactive amino-acid; the effect is shown graphically in Fig. 1.

In a series of experiments the chase was added at times varying between 4 min and 20 min. While longer periods of labelling give a less selective labelling of microsomes, it was obvious in every experiment that, after the chase, there was a rapid release of labelled protein from the microsome fraction and that the bulk of this radioactive protein appeared in the cell sap. It will be noted that there is a significant but small increase in the radioactivity of the mitochondrial protein after addition of chaser. While this type of experiment is only indicative, the ab-sence of any close resemblance between the kinetics of labelling of mitochondrial protein and cell sap protein certainly suggests that a limited amount of mitochondrial protein is synthesized independently of the microsome-cell sap complex. As cytochrome *c* was not labelled when mitochondria were incubated *in vitro* with a labelled amino-acid[4] this protein was the obvious choice for further

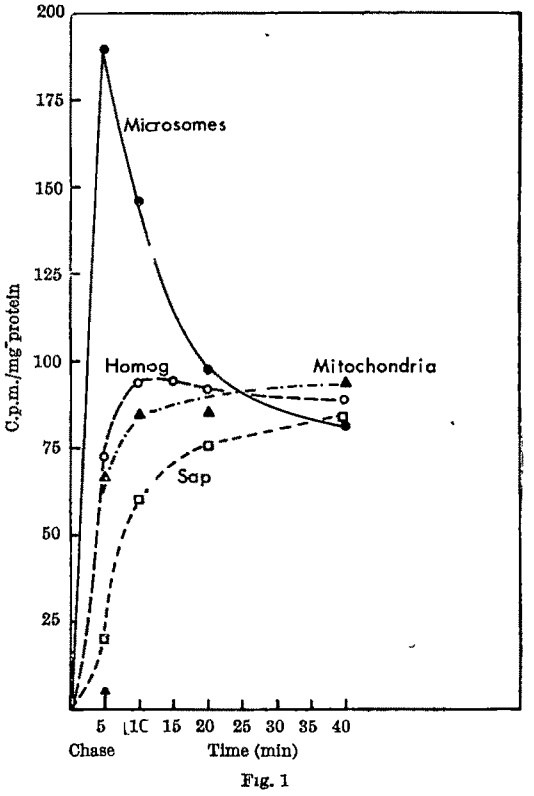

Fig. 1

investigation. As can be seen from Table 1, the labelling of cytochrome *c* in the absence of a chase resembles that of whole mitochondrial protein. If, however, a chase is added to the cells at 30 min the subsequent increase of specific activity of cytochrome *c* is substantial (60 per cent), but the change in specific activity of whole mito-chondrial protein is negligible, there being, if anything, a decrease in specific activity. This result suggests that the peptide chain of cytochrome *c* is synthesized on non-mitochondrial cytoplasmic ribosomes but that some other mitochondrial proteins are synthesized by a separate intramitochondrial protein synthesizing system.

These experiments encouraged us to take as our working hypothesis the assumption that mitochondrial proteins are synthesized by two independent routes. We suppose that one group of proteins is synthesized inside mitochon-dria and the other group is synthesized on non-mito-chondrial cytoplasmic ribosomes and later transferred to

Table 1. LABELLING OF CYTOCHROME *c* WITH ^{14}C-VALINE BEFORE AND AFTER A CHASE OF ^{12}C-VALINE
(Results expressed as mμc /mg protein)

Fraction	Time of incubation and treatment: 20 min	60 min, no chase	60 min, chase at 30 min	Remarks
Whole homogenate	233	411	217	Chase stops labelling
Whole mitochondria	296	540	247	" "
Cytochrome *c* (1)	50·7	126	81·5	60 per cent increase after chase
Cytochrome *c* (2)	52·5	—	89·5	" "
Cell sap*	35	—	72	101 per cent increase after chase

* Separate experiment, chase added at 20 min.

* Substance of an address given by Dr. T. S. Work in Glasgow on April 18.
† Overseas scholar of the Royal Commission for the Exhibition of 1851.
‡ Present address: Department of Biochemistry, McMaster University, Hamilton, Ontario, Canada.
§ The Krebs II ascites tumour is a cell line which originated as a mammary carcinoma and was adapted to growth as a free-living form of cell which can be propagated in the peritoneum of the mouse (Klein, G., and Klein, E., *Cancer Res*, 11, 466; 1951).

the mitochondria, possibly as porphyrin-free unfolded peptide chains (mitochondria can certainly synthesize porphyrins[6]). In seeking confirmation of this hypothesis, we measured the effect of a whole series of inhibitors on the synthesis of microsomal and mitochondrial proteins in Krebs ascites tumour cells. With the concentrations used, none of the classic inhibitors of protein synthesis showed any selective inhibition of one or other of these two postulated independent systems. We had found in earlier incubations of mitochondria *in vitro*, however, that ribonuclease had no inhibitory effect on mitochondrial protein synthesis, presumably because the enzyme failed to penetrate into the organelle[6]; whereas it is well known that microsomal protein synthesis is inhibited by ribonuclease. Conditions were sought, therefore, for the introduction of ribonuclease into intact Krebs cells. Ribonuclease added to a suspension of normal washed Krebs cells has no effect on protein synthesis, but if cells suspended in buffered saline + ribonuclease are osmotically shocked by adding seven volumes of water, briefly incubated, then restored to an isotonic medium and incubated with ^{14}C-valine, it is found that the presence of ribonuclease has induced substantial inhibition of protein synthesis. The results of one such experiment are shown in Table 2.

Table 2. INHIBITION OF PROTEIN SYNTHESIS IN KREBS CELLS EXPOSED TO HYPOTONIC SHOCK AND RIBONUCLEASE

Period of osmotic shock	Concentration of ribonuclease (μg/ml.)	Counts incorporated (per 1×10^8 cells)	Percentage of inhibition by ribonuclease
0*	0	3,300	—
0*	100	2,660	20
5	0	1,053	—
5	100	800	24
15	0	399	—
15	50	328	18
15	250	209	47
15	500	152	62

Washed Krebs cells (6×10^8 in 4 ml. of phosphate buffered saline) were poured into 28 ml. water containing ribonuclease. At various intervals thereafter osmotic pressure was restored to normal and a sample of cells was incubated at 37° C with ^{14}C-valine for 15 min.

* It is not possible to carry out all the necessary operations in zero time and in fact these cells were exposed to osmotic shock for perhaps 30 sec before tonicity was restored to normal.

The strong inhibition of protein synthesis induced by osmotic shock even in the absence of ribonuclease seemed to indicate at first that we had damaged the cells irreversibly; nevertheless, shocked cells could be propagated in the mouse peritoneum and in rate of growth they could not be distinguished from fresh cells. In accordance with expectation, synthesis of mitochondrial protein was less inhibited by ribonuclease than was synthesis of microsomal and cell sap proteins. The results of two experiments are given in Fig. 2. In each experiment cytochrome *c* was isolated after addition of mouse liver cytochrome *c* as carrier. It will be noted that the inhibition of incorporation of isotope into cytochrome *c* was of the same order as the inhibition of microsomal protein synthesis whereas the synthesis of total mitochondrial protein was much less inhibited.

It is difficult to explain these results except by the assumption that the peptide chain of cytochrome *c* is synthesized on the non-mitochondrial cytoplasmic ribosomes whereas the peptide chains of some other mitochondrial proteins are synthesized by a separate system resistant to ribonuclease and presumably therefore inside pre-existing mitochondria. It must be emphasized that we do not propose the existence of two mechanisms for protein synthesis but rather the existence of several independent sites separated by barriers impermeable to ribonuclease but with selective permeability for cytochrome *c* peptide.

Despite their plasticity (indicated by our opening quotation) mitochondria are well-defined complex multimembrane structures. It is impossible to say precisely how many proteins are present in the typical mitochondrion, but a survey of the literature indicates that something of the order of at least twenty soluble and twenty insoluble proteins are likely to be involved in the formation of this one organelle. There is good evidence both from electron microscopy[7] and from comminution and reconstruction experiments that most and perhaps all of these proteins are fitted together in an orderly repeating pattern[8].

In earlier investigations of the synthesis of mitochondrial proteins *in vitro* we found that, while isolated mitochondria could readily incorporate labelled amino-acids into protein, very little of this radioactivity was found in the soluble readily extractable proteins[9]. These proteins constitute perhaps one-quarter of the total protein of liver or Krebs cell mitochondria, and as a result of our present investigation we now suggest that these proteins are synthesized on non-mitochondrial cytoplasmic ribosomes under the control of an RNA code supplied by the nucleus.

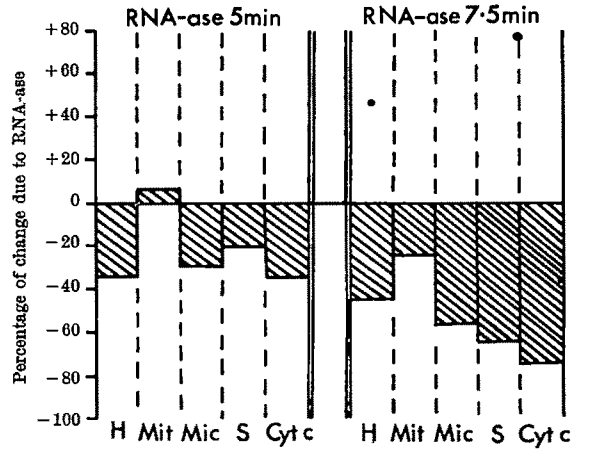

Fig. 2. The inhibition of protein synthesis in Krebs ascites tumour cells after osmotic shock in the presence of ribonuclease. In the first experiment the duration of osmotic shock was 5 min, in the second 7·5 min at 37° C. After shock, cells were incubated for 15 min and 20 min, respectively, in isotonic buffered glucose containing ^{14}C-amino-acid. At the end of this time cells were disrupted and individual fractions isolated by the appropriate methods

While the classic work of Ephrussi on petite mutants of yeast and of Sonneborn on extrachromosomal determinants of phenotypic character in *Paramecium* strongly suggested the existence of extrachromosomal genes (plasmagenes), it is only in the past 18 months that conclusive evidence has become available[1] that several types of mitochondria, including Krebs cell mitochondria[10], contain DNA. There is no direct evidence as yet that this DNA controls protein synthesis, but it is certainly pertinent to ask whether such evidence can be found. As a first approach to this problem, we re-examined the pattern of incorporation of radioactive amino-acids into the insoluble proteins of liver mitochondria during incubation of intact washed mitochondria in buffered sucrose with succinate as energy source. The insoluble mitochondrial proteins are not solubilized by the orthodox techniques of protein chemistry, but they can be obtained in solution by extracting mitochondria with a mixture of sodium dodecylsulphate, sodium-deoxycholate and sodium-cholate[11]. Addition of ammonium sulphate under suitable conditions leads to the precipitation of a fraction which Green and his colleagues have described as mitochondrial structural protein. This material constitutes nearly half the entire protein of ox heart mitochondria, but it possesses no known enzyme activity; nevertheless it seems to be an essential component which must be present before any part of the electron transport chain can be reconstructed by addition of dehydrogenases and cofactors. Some time back[12], Roodyn, in this laboratory, applied the Green technique to liver mitochondria previously labelled by incubation

in vitro with ^{14}C-valine. He found that the Green structural protein fraction was radioactive. We have recently found that this fraction prepared from liver mitochondria is a mixture of several proteins and that it can be successfully resolved into a number of discrete protein bands by electrophoresis in acrylamide gel using as solvent either a mixture of sodium dodecylsulphate and urea in phosphate buffer[13], or alternatively a mixture of phenol, acetic acid and water[14]. The number of components present was discouragingly large, so we tried instead the more recent improved method for preparation of structural protein[15]. This method, applied to liver mitochondria, yielded a multi-component product, but four major bands were readily resolved on acrylamide and it seemed worthwhile to analyse the distribution of radioactivity on an identical gel. This was done using a gel homogenizer[16], and the results are shown in Fig. 3.

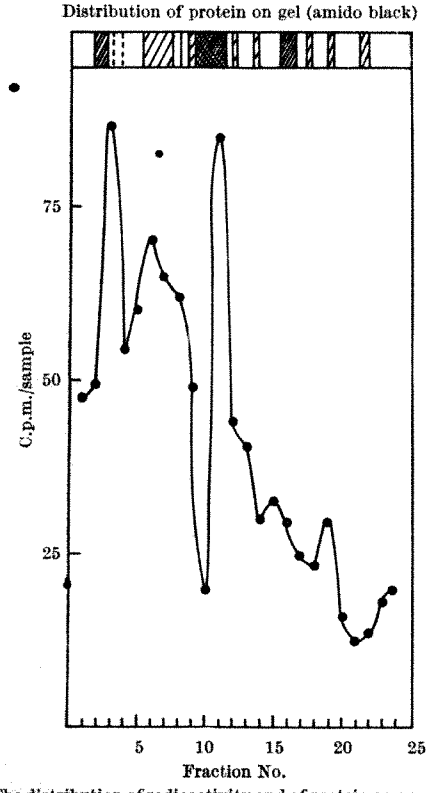

Fig. 3. The distribution of radioactivity and of protein on an acrylamide gel after electrophoresis of 400 μg of structural protein prepared from liver mitochondria. The mitochondria were incubated with ^{14}C-protein hydrolysate in buffered succinate for 1 h (ref. 9)

It is obvious from the diagram that several distinct proteins become labelled when mitochondria are incubated *in vitro* with labelled amino-acids. It occurred to us that we might be able to identify one of these bands by comparing it with Racker's coupling factor-4* (one of the major insoluble structural proteins of the mitochondria) which has been obtained in a state approaching purity[17]. Dr. Racker very kindly supplied us with a sample of his coupling factor-4 and this was fractionated on acrylamide at the same loading and under exactly the same conditions as our radioactive structural protein. The resulting gels were stained and photographed side by side (Fig. 4). It appears from Fig. 4 and from Fig. 3 that one of our major radioactive bands is similar to Racker's coupling factor-4. It must be emphasized, however, that we have not unequivocally identified one of our radioactive bands with Racker's coupling factor-4, and full characterization awaits isolation in quantity and fingerprinting of the radioactive bands. It seems reasonable, however, to extend our working hypothesis and to propose that mitochondrial DNA may code for a limited spectrum of insoluble proteins which form a part of the mitochondrial matrix. (Since this article was prepared, it has been suggested that mitochondrial structural protein of respiration deficient mutants of *Neurospora* differs from the structural protein of wild type in its amino-acid composition—Woodward, D., and Munkres, K., *Proc. U.S. Nat. Acad. Sci.*, **55**, 872; 1966). This extension is supported by the studies of Kalf and Gréce[18], who have obtained evidence that when lamb heart mitochondria are incubated with ^{14}C-amino-acids *in vitro*, the adenosine triphosphatase (ATPase) of the mitochondria becomes radioactive and that the radioactivity does not result from terminal addition of radioactive amino-acids to pre-existing protein.

* Racker's coupling factor-4 is one of four proteins required for the full coupling of phosphorylation to oxidation of substrate by partially disintegrated mitochondria.

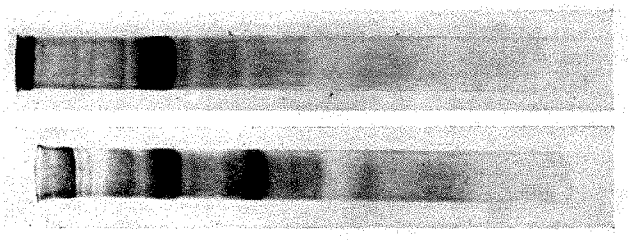

Fig. 4. Comparison between Racker's coupling factor-4 and structural protein from rat liver mitochondria. Both gels were heavily loaded with protein (400 μg) so as to show up minor bands and were afterwards stained with amido black

We can, so far, provide no direct evidence for the function of mitochondrial DNA, but we already know that mitochondria can incorporate thymidine into mitochondrial DNA *in vitro* (Fig. 5) as well as *in vivo*, that mitochondria contain a DNA-dependent RNA polymerase[19], that amino-acid activating enzymes are present in the soluble protein extracted from mitochondria[3] and that isolated mitochondria can incorporate radioactive amino-acid into certain insoluble proteins. The mere fact that when mitochondria are thus incubated some proteins are strongly labelled, whereas other equally typical mitochondrial proteins are entirely unlabelled, is a powerful argument for assuming that the labelling which occurs *in vitro* is a genuine and selective protein synthesis. The fact that this synthesis *in vitro* is inhibited by both puromycin and *cycl*oheximide strongly suggests that it is proceeding by essentially the same mechanism as that already characterized for the cytoplasmic ribosomes. Indeed, it may be advisable to introduce a slight modification of present nomenclature and to suggest two new terms—"cytoribosomes" and "mitoribosomes"—to describe the ribosomes of the extramitochondrial and of the intramitochondrial protein synthesizing systems.

In the light of these results it is informative to review various observations recorded for biological systems of widely differing complexity. In such a review there is an obvious element of risk because we cannot be equally expert in all disciplines, but if we rush in like fools perhaps we may be forgiven if we trip over facts which by their very familiarity may sometimes be invisible.

So far as we are aware, bacteria contain no centriole, no basal body or kinetoplast, no mitochondria and no plastids. Nevertheless, aerobic bacteria do contain cytochromes, flavoproteins and quinones and use a series of coupled enzyme reactions for the aerobic oxidation of acetate which closely resembles that found in higher forms; some even show glucose repression and oxygen induction of the cytochrome system closely resembling that found for yeast mitochondria[20].

Many forms of bacteria do develop before division a complex membranous structure which appears to be

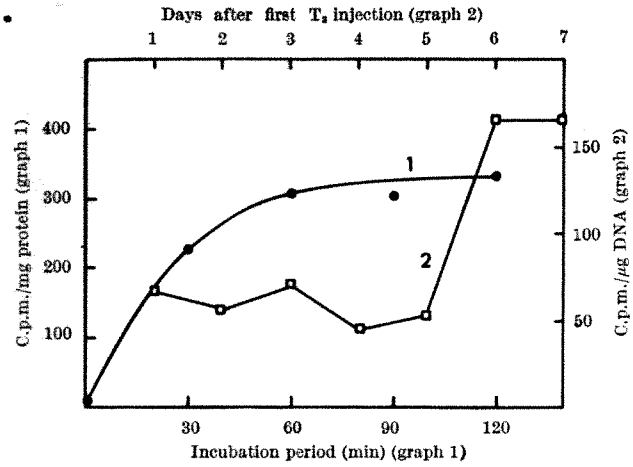

Fig. 5. The effect of repeated injection of triiodothyronine into thyroidectomized rats on the rate of incorporation of radioactive thymidine into mitochondrial DNA. Graph 1 shows the kinetics of incorporation during incubation of a single sample of washed liver mitochondria incubated under the usual conditions. In Graph 2 each point represents the mean value for the mitochondria obtained from the livers of three rats treated as indicated

formed by invagination of the plasma membrane. This structure, now usually referred to as the mesosome region, shows some of the character of a primitive mitochondrion in that it reduces tetrazolium; it also exhibits some of the character of a centriole as it seems to initiate the separation of the bacterial chromosomes[21]. Add to this the observation that in the primitive ciliates the mitochondrion and the kinetoplast form a single body[22], that in various higher forms the kinetoplasts, the mitochondria, the basal bodies and the plastids all seem to contain traces of DNA which can be lost (provided loss is not lethal), that moreover the photosynthetic apparatus of the plastid has many biochemical similarities to the mitochondria[23], and one seems almost forced to suggest that the mesosome which had the capacity to attach to the bacterial chromosome may well have, during evolution, acquired a few of the chromosomal genes and then to have differentiated further into the various related structures of higher forms, namely, the centrioles, the mitochondria, the kinetoplasts, the basal bodies and the plastids. If this were indeed so, we might well expect that the same type of DNA-dependent DNA polymerase would be responsible for the replication of the DNA of all these bodies. There are, it seems, a few hints that this is so; for example, one such polymerase seems to be present in both nucleus and cytoplasm of fibroblast cells, and this polymerase is concentrated in the nucleus during periods of chromosome replication but released into the cytoplasm during interphase[24]. Moreover, in the sea urchin embryo it has been reported that mitochondrial formation and mitotic activity are antagonistic[25]. We thought, therefore, that because thyroxine is known to induce mitochondrial hyperplasia in animals[26] it would be interesting to measure the effect of thyroid hormone on the rate of DNA synthesis and on the DNA level in rats injected with triiodothyronine. We found that when thyroidectomized rats were given repeated injections of triiodothyronine, there was little effect on DNA level or on the rate of DNA synthesis for 5 days. On the sixth day, however, as shown in Fig. 5, isolated rat liver mitochondria showed an increased ability to incorporate tritiated thymidine, and by the seventh or eighth day the DNA level in rat liver mitochondria was increased by as much as three-fold (per mg protein) compared with controls.

We scarcely need to direct attention to the interesting problems in control which are presented by the existence of a number of extra-chromosomal genes, the reading of which must be fully integrated with the reading of chromosomal genes so that the right proteins are fitted together in the appropriate order to produce functional mitochondria. It is noteworthy that few mitochondrial proteins failed to penetrate acrylamide gel (10 per cent monomer) and this would imply an average peptide molecular weight below 40,000. Nevertheless, many mitochondrial enzymes, especially the more firmly bound enzymes, are of extremely high apparent molecular weight[8]. It would, therefore, not be unreasonable to suppose that the majority of these enzymes are aggregate structures compounded of a number of distinct peptide chains. It is obvious from the investigations of Slonimski *et al.*[27] that a whole spectrum of nuclear genes controls mitochondrial maturation and the synthesis of cytochrome enzymes in yeast. It could well be, therefore, that some of the multi-chain enzymes of the mitochondrion depend on nuclear genes for one chain of a multi-chain structure but on mitochondrial genes for some other parts of the aggregate three-dimensional active enzymes. Even in those acridine mutants which lack some mitochondrial DNA (ref. 28) there is a primitive form of mitochondrion[29]. This primitive mitochondrion has some structural resemblance to a mesosome and perhaps contains a lipoprotein similar to that of the primitive mesosome. Moreover, the recent investigations of Jakob[30] on complementation between respiratory mutants of *Saccharomyces* strongly suggest that there is a coupled interaction between the chromosomal genes and the cytoplasmic genes of respiration-deficient mutants. Such coupling might be expected if the reading of two or more entirely independent polycistronic messengers had to be integrated before a functional mitochondrion could be produced.

By the Nuclear Research Foundation School Certificate Integrated Science Textbook Group of Authors and Editors, under the Chairmanship of H. Messel. (Sydney: Nuclear Research Foundation within the University of Sydney; London: Pergamon Press, Ltd., 1964, 1966.)

THESE science text-books were designed to provide a complete science course for secondary pupils in the schools of New South Wales, but the authors hope that they will be found useful elsewhere. The first 4 years of the course are covered in *Science for High School Students* (SHS), while the final 2 years are distributed between the three separate volumes of *Senior Science for High School Students* (SS). *Science for High School Students* is available in two formats: a library edition complete in one volume and a classroom and laboratory edition in two separate volumes. An abridged edition has also been designed for use by pupils following the Ordinary Level course. (The unabridged edition is intended for those taking School Certificate at the Credit or Advanced Level.) A manual for teachers has been prepared for both *Science for High Schools* and *Senior Science for High Schools*. Appearing as they do some years after the various American courses and just before the publication of the Nuffield texts in Britain, these books are of more than usual interest.

The general SHS volume is very full in content and covers elementary physics, chemistry, biology and geology with encyclopaedic thoroughness. It suffers, however, from the main disadvantage of other texts of this kind: it gives the pupil all the facts without any reference to the way in which the content is actually to be taught in the classroom. Many experiments are described, but there is little to indicate that they are part of a consistent course in which the pupil, his experiments, the teacher and the text all have a part to play in the learning process. An extreme example of this comes early in the first chapter where the pupil in almost his first lesson meets the Bohr atom, nucleons, elements and compounds. How can there be any hope that the pupil will think critically about his science when he is introduced, at the very outset of his course, to a series of facts about the more crucial concepts of physical science designed for ready acceptance?

SHS is written for use over a wide range of age. When a pupil starts on the course he is twelve and he passes to the succeeding volumes when he is sixteen. It is therefore surprising to find little variation in reading difficulty between the prose of the earlier and later chapters. For example, the following sentence occurs very early in the abridged version, and is intended for 12-year-old pupils about to follow the ordinary course, and thus unlikely to be among the most able: "Nevertheless Democrites would have reasoned: suppose that I imagine that I have a perfect tool and that I can keep on dividing the material for as long as it is divisible—can I keep going for ever, or will I eventually have the smallest piece of matter which is indivisible?"

The *Teachers' Manual* is helpful; it contains hints on the experiments in addition to sources of material and questions. The balance of the course would have been improved if more emphasis had been placed on this manual and thus on the teacher. In the pupils' book, the result of an experiment is given almost in the same breath as the experiment itself. How much better if the result had only appeared in the manual together with the development following from the experiment. (These comments also hold good for the *Teachers' Manual* to SS.)

These criticisms are directed at SHS as part of the school learning situation, and should not be allowed to detract from the obvious thoroughness and care which have gone into the writing. Many of the sections are models of clarity and compression. Among examples of these is the discussion of fields on pages 42–46 and 42–47. The geology content, which is very full, is not usual in British courses of a similar kind, but it fits naturally into these text-books. Here, at least in Britain, we are given cause to examine our own neglect of the subject, and also of astronomy which receives similar extended treatment. Many teachers will find SHS useful, especially those sections covering other than their own speciality.

The senior course has been conceived as a whole, and because of this there is no wasteful overlap between the three parts into which it has been divided. There is, however, a deliberate overlap between the content of the more advanced *Senior Science* and that of the more elementary *Science for High School Students*. Part 1 is solely concerned with physics, and is an unusual book. There is no reason to doubt the authors' claim that certain concepts and the mode of their presentation have never before appeared in a school text. In Britain, books at this level tend to be written by schoolmasters and, although usually reliable and sometimes distinguished, are usually derived works and seldom contain anything so fundamentally different as to give one a mental start. The physics section of SS does just this. It continuously excites and makes the reader eager to press on and follow a theme to its conclusion. Those of us who work in schools have reason to thank members of university faculties who give part of their time and energy to write texts of this nature.

To some degree the content follows general modern trends. There is little calorimetry; Joly's differential steam calorimeter is not the ghost at this feast. Geometrical optics, transfer of heat-energy and electrical circuit theory are only covered to a standard somewhere below Ordinary Level in Britain, and the space and time so gained are used adventurously. First comes a most careful treatment of dynamics. Points that are all too often passed over briefly are given more extended attention; examples are the discussions of action and reaction, and of inertial forces in circular motion. No use, however, is made of the calculus, here or elsewhere, and this leads to some difficulties.

A treatment of electricity and magnetism follows, in which the latter is treated as a second-order effect. It is made clear at the outset that the student is asked to regard magnetism as inevitable given Coulomb's law and the transformations of special relativity. The derivation of the law of force between current-carrying conductors is approximate and depends on low charge-velocity. This is the section which makes the book unique as a school text. There has been a growing body of opinion that special relativity ought to be formally taught in schools, and this

book makes it possible for us to estimate the feasibility of such a step. A discussion of wave theory leads to a very clear section on the wave nature of matter. This is very fine and will serve as a source of inspiration to all who teach these topics.

A text-book cannot be judged apart from its intended users. It is to be hoped that a strong feeling that the majority of pupils at the late secondary stage will find this book very hard going indeed will prove ill-founded. For this reason, reports on the reactions of such students in Australia to the book are eagerly awaited.

A few points give rise to queries. The coulomb is first defined as a certain number of electronic charges. Later Millikan's experiment is described and the outcome given in terms of coulombs. It would seem in fact that it is the permittivity of free space which is arbitrarily assigned, but the point is clouded—possibly deliberately. The mathematical analysis is regrettably printed in a very cramped manner.

The other two SS volumes are more orthodox in character. Part 2 contains a coherent and didactic account of modern chemistry. The theme begins with a traditional description of the behaviour of gases, reactions between gases, and formulae and equations. At this stage, a less conventional but reasonably clear and simple account of energy in chemical reactions and bonding is introduced. This is followed by a consideration of the elements of the Periodic Table and their halides and oxides. The history of atomic structure is dealt with in a section which precedes a modern introduction to structure which includes reference to the Born-Haber cycle. The final part of the text is directed at an up-to-date look at chemical change from the point of view of equilibria, acids and bases, electron transfer mechanisms and rates, and oxidation states. Organic chemistry is crammed for the most part into two chapters—one under the guise of the hydrides of carbon and the other on substitution and addition compounds.

Some criticisms of the details of the text should perhaps be given. The most important of these concern the introduction to formulae and equations. This is very conventional and makes no use of the mole concept. A small but important point which should be corrected concerns the energy diagrams, such as they are. The higher energy species are shown at the bottom and lower energy at the top: this is most confusing!

On the face of it, the text is clear, straightforward and modern. But this book represents the complete standard work for chemistry at senior high school level in New South Wales. What do the students actually do? Do they listen to expositions by the teacher and then read the book? What experiments do they perform? The experimental work in the book is very weak, and few experiments are inserted at the end of each chapter. Although some of these experiments are "open ended", their position at the end of the chapter implies that they are confirmation for, or illustrations of, the theories which have been expounded in the preceding text. In no case does the need for this theory derive from the evidence of an experiment. It may be, of course, that there is a great shortage of laboratory space in New South Wales. In Britain the tradition of chemistry as an experimental subject dies hard, and new movements in the teaching of chemistry are aimed at making Advanced Level courses even more laboratory-based. The New South Wales course is clearly text-book based. To our eyes, therefore, despite its modern content. Part 2, on chemistry, has an old-fashioned look.

Part 3, on biology, is an authoritative and informative book arranged in three main sections. The first deals with Darwin and evolution, Mendel and genetics, variation and the modern view of natural selection. This is followed by an excellent discussion on the diversity and abundance of species and an investigation of the effects of environment on populations. Ideas new to this level are included, for example underpopulation and crowding. In the section on population, examples from Australian ecology are used to illustrate features of ecology, which makes a pleasant change from time-worn European situations. The second section is a treatment of three particular aspects of an individual organism: reproduction, control and co-ordination and behaviour. Some modern material is included but the treatment is very ordinary. The final section on cell structure and function uses much biochemistry and electron microscopy and is an up-to-date and authoritative account. The ground covered in these topics is dealt with in a logical and concise manner: the general level is about that of the present Advanced Level in Britain.

The main difficulty with Part 3 is that its approach to biology is not one of enquiry and investigation depending on practical observation and experiment. In fact, the practical section of the book is relegated to twenty pages at the back and the whole emphasis of the text is one of encyclopaedic coverage of a series of complex topics. Each chapter is provided with a group of questions, often well designed, but they are based on the text rather than on experiment.

In general, this is an interesting volume that could be of considerable value to teachers as a book of reference and to pupils as a background reader. However, the general approach runs counter to present trends in the teaching of biology in Britain, which seek to make the subject an activity of experiment and discovery.

A select bibliography follows many of the chapters in the SS volumes and especially in Part 3; this will help the pupil considerably in his selection of "follow up" reading. Throughout the books, pages are identified by chapter: thus a page labelled 36–15 is the fifteenth page of Chapter 36—in places the index is somewhat confusing because of this system.

The criticisms which we have made stem, in the main, from a divergence between our conception of the function of a science text and that of the authors. However, the drive and industry which have gone into the production of these volumes are obvious to all. Prof. Messel and his colleagues are to be congratulated on the completion of this huge task—done in record time. Their efforts can only encourage and inspire all engaged on the refashioning of science courses.

THE MOON IN PICTURES

Photographic Atlas of the Moon

By Zdenek Kopal. Pp. 277. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 128*s*.

THIS book represents part of the latest in a now considerable series of systematic photographic surveys of the Moon. Sponsored by the U.S. Air Force Aeronautical Chart and Information Center, more than forty thousand exposures of all or part of the Moon were obtained at the Pic du Midi by a team from Manchester led by Kopal, to produce the largest homogeneous set of lunar photographs ever made. 300-m contour charts have been produced from these.

The present work consists of three introductory chapters, a selection of 217 prints taken from the total amassed so far and nine photographs from the *Ranger VII* series. The first chapter is essentially a presentation of the physical properties of the Moon, the main topics being the characteristics of the orbit, the librations, mass and density, internal structure and conditions, and a lengthy consideration of the possibility of a gaseous atmosphere.

Following a brief description of the familiar surface features, the second chapter is concerned with the origin

of the larger ones. Attention is given to both external and internal processes, particularly for the formation of ring structures, but the origin of the surfaces of the maria, and also of domes, rilles and wrinkle ridges, are considered. An outline of the chronology of lunar structures is given using the criteria of overlap, ruggedness and albedo for dating purposes.

The third chapter considers the detailed structure of the lunar ground. The evidence from photometric, polarimetric, thermal and radio investigations is presented well, with only one obvious error—the phase at which the plane of polarization of moonlight rotates by 90° is given as the quadrature, when in fact it has the value of about 23·5°. In the interpretation of the data, however, several points of controversy arise. The undoubtedly vesicular nature of the surface is attributed to small crater-pits produced by micro-meteorites in the overlying coating of interplanetary dust; the difference in albedo between maria and continents is explained as due to inmixing of native material by more energetic impacts. This argument ignores two points: it has been shown by several workers that no combination of regular crater pits can fully reproduce the lunar photometric curves, some degree of interconnexion between adjacent pores being almost certainly necessary; and also that falling interplanetary dust will probably build up a dendritic "fairy-castle" structure in any case. Both these points deserve mention, as does the often neglected possibility that the differences between maria and continents may not only be those of albedo: as any sufficiently vesicular dust or rock may have most of the lunar properties, the two types of area could be quite different in origin, as would be the case if the maria were relatively recent flows of vesicular lava.

In terms of absolute resolution the photographs given do not represent any improvement over, for example, the *Photographic Lunar Atlas* edited by Kuiper, but do have the advantage of homogeneity, making intercomparison of different areas more meaningful. In general this work is a useful addition to the literature on lunar surface problems by way of a review. Perhaps no single work can cover every facet of the subject, but this book presents an outline of the appearance and nature of the Moon adequate for many purposes.

L. WILSON

BACKWATER OF SCIENCE

Melting and Crystal Structure

By A. R. Ubbelohde. Pp. xi + 325. (Oxford: Clarendon Press; London: Oxford University Press, 1965.) 63*s*. net.

Melting and Crystal Structure is mainly concerned with the principal thermodynamic parameters of melting, particularly melting points and the changes of entropy and volume at melting, and the attempts which have been made to understand what regularities can be perceived in these parameters. There is little detail with regard to crystal structure, and "Melting and Molecular Motions" would have been a more accurate title. Save for one chapter on "Rate Processes in the Solid–Liquid Transition" (chiefly nucleation), and another on glasses, the book concentrates on equilibrium properties. If a good monograph is one of which one can say, "Read this; accept it, and use it to light your path in neighbouring fields of science", this does not qualify as such, but if the test of merit is whether it is likely to promote the advance of natural knowledge, it can. For no one can read this book without the conviction that there is much more yet to be discovered about even so simple a phenomenon as melting, at every level from the most to the least sophisticated. The good book in the former sense could scarcely be written, because the basic data are often missing or unreliable. One would like to be able to congratulate the author for bringing the data, such as they are, together. Unfortunately, at any one place he usually quotes only a single value, without declaring a basis of selection, and repeated data seldom agree with precision.

The author himself directs attention to the substantial discrepancies between dT_f/dp and the ratio of directly measured ΔV_f and S_f (12 per cent discrepancy for sodium chloride: page 142). It should be sobering for scientists, taking pride in their achievements over the really difficult measurements, to appreciate the paucity of reliable data on such elementary matters as these. Ought we to tolerate this situation? How can we complete the surveys in areas which science has passed by on the way to the frontiers? Why should only graduates get that incentive to do their best in a measurement which comes from knowing that it produces new knowledge, which someone needs? Schoolboy athletes try to do better than has been done before: why should not schoolboy scientists? In Britain, about 50,000 people each year take Advanced Level examinations in physics and chemistry: with a little organization they could contribute measurements of latent heats and dilatations at fusion for a host of substances in the easy temperature range, say 0°–200° C, with such multiplicity of independent checks that the reliability of the results should be easy to ascertain. Some enterprising schools, and some undergraduate laboratories, could extend into more difficult temperature ranges: and a few of those involved would come to appreciate the worth of more thorough research, say into the thermodynamics of melting at constant volume.

Against a background of imperfect data, the theory of the subject remains, apart from the basic thermodynamics, a mixture of near misses (such as the Lindemann melting point formula, percipient when new, but something which surely ought to have been overtaken by deeper understanding by now), crude though instructive models (such as theories of melting which still leave the liquid molecules on a lattice) and wild ideas often stemming from dubious experimental observations. The author cites them systematically, with perhaps too uniform a sceptical deprecation: for he tends to be tentative in introducing the obvious or even the necessary.

A chapter on liquid crystals contains an interesting miscellany of citations, but its very brief section on cholesteric phases, when contrasted with Friedel's article (*Annales de Physique*, 18, 273; 1922), serves remarkably to illustrate the way in which scientific understanding can lapse in a field which is not continuously cultivated.

F. C. FRANK

POSITIVIST MEASUREMENT

Basic Concepts of Measurement

By Brian Ellis. Pp. ix + 220. (London: Cambridge University Press, 1966.) 45*s*. net; 8.50 dollars.

THE aim of this book is "to give a consistent positivist account of the nature of measurement", which is regarded as "a central concern of the philosophy of science". It is clearly written; the author faces the problems honestly and does not hesitate to say when he has failed to solve them, and the book is a lively stimulus to thought.

It has, however, one fundamental defect, which appears to arise from the desire to regard the commonsense and scientific views of the world as expressible in the same terms. This is impossible, and if possible would be undesirable. There is no reason why the astronomer should be forced to express terrestrial rotation in terms of sunrise, or why, in daily life, we should speak of dawn in terms of the position angle of the Earth. In shopping, measurement is always measurement of a quantity of something already there—a pound of bacon, a yard of

cloth. In science, on the other hand, the measurement is primary, and there may or may not be a "thing" which is measured. What thing lies behind the altitude of the First Point of Aries? The spectroscopist measures λ, and afterwards chooses whether to call it the length of a wave or the reciprocal of the momentum of a particle: he does not first observe the wave or particle and then measure one of its properties. It follows that a true fundamental account of measurement must not presuppose a metaphysical something of which the measurement ascertains the magnitude.

Mr. Ellis's account is based on the presupposition that every measurement is the measurement of a "quantity" possessed by a "thing". He has then to define "quantity", and his "final position" is that it depends on "the existence of a set of linear ordering relationships"; he leaves it to others to decide which quantities are entitled to be given names. On this definition probability, for example, is a quantity, and it is discussed at length. It is scarcely too much to say that all the problems dealt with are created by the unnecessary introduction of quantities, and the acuteness of the analysis does not compensate for its superfluity.

Nor are quantities merely superfluous; their introduction as entities prior to their measurement (there is, of course, no reason to forgo the convenience of using such terms as wave-length for descriptive purposes) is a fundamental error, for it misrepresents empirical discoveries as logical necessities. Thus, the agreement between measurements of distance by laying rods end to end and by triangulation follows inevitably on the "quantity" assumption, for they are measurements of the same thing. When there is reason to think that it breaks down over long distances, all we can do is to try to discover which method is "right". But if we regard both as valid but different measurements the results of which are approximately equal, their disagreement over long distances reveals an important fact about the universe. Whether it is best described as the curvature of space or the non-rectilinear propagation of light or what not can then be discussed, but in any case it is a discovery about the universe which the presupposition of quantities would have made impossible.

HERBERT DINGLE

HIGH-ENERGY NUCLEAR PHYSICS

High Energy Nuclear Reactions

By A. B. Clegg. (Oxford Library of the Physical Sciences.) Pp. vi+130. (Oxford: Clarendon Press; London: Oxford University Press, 1965.) 18s. net.

NUCLEAR reactions induced by low-energy nucleons are usually complicated processes, but at higher energies in the region above 100 MeV and for light target nuclei a great simplification is possible in certain types of reactions. This book is especially concerned with reactions induced by protons and neutrons in the energy region between 100 and 400 MeV, in which a simple change is made in the target nucleus. In this case it is possible to understand the reaction mechanisms in some detail and in some instances also to obtain information about the structure of the nuclei involved.

In the first chapter it is pointed out that at these energies the incident nucleon frequently interacts with only one nucleon at a time, and in subsequent chapters the reactions considered are those in which only one collision with a nucleon changes the state of the nucleus. In the next chapter the reasons why this type of reaction is likely to occur are discussed and the matrix elements involved are related to the nucleon–nucleon scattering amplitudes. Distortion effects on the incident and outgoing waves are next considered and the quasi-classical approximation introduced. The third chapter is concerned with the experimental features of the investigation of high-energy nuclear reactions and contains a brief discussion of the measurement of particle energies, the measurement of γ-ray energies from the decay of excited states and polarization phenomena in nuclear reactions.

Chapter 4 discusses the elastic scattering of nucleons by nuclei. Here the treatment in some places is brief and not complete because several other books have recently been published on the theoretical analysis of elastic scattering data using the optical model. Dr. Clegg instead concentrates on the relationship to the nucleon–nucleon scattering amplitudes, and an extensive comparison is made between the theoretical calculations and the available experimental data. The contributions from spin-flip and isotopic spin-flip processes are considered in some detail.

Chapter 5, which is by far the longest in the book, is concerned with inelastic scattering. Using the plane-wave approximation the contribution from spin flip effects are considered together with the information which can be obtained from the angular distribution of γ rays from the excited nucleus. Distorted wave calculations are then introduced and the effects due to a spin-dependent distorting potential are found to be small. These calculations are then compared with the experimental measurements of the polarization and angular distributions and where possible related to the nucleon–nucleon scattering amplitudes. Other excitation mechanisms which might contribute to inelastic scattering reactions and how they can be related to single nucleon excitation are then considered.

Nucleon knockout reactions in which the incident nucleon collides with a nucleon in the nucleus with the result that both nucleons leave the otherwise undisturbed nucleus are dealt with in the next chapter. After a brief discussion of (p,d) reactions, $(p,2p)$ reactions are considered in great detail, especially the interpretation of the results in terms of the shell model. In the final chapter reactions in which a cluster of nucleons are ejected from the target together with a nucleon are discussed. Although a comparison with experimental results is difficult because of the lack of data there is an extensive discussion of the relationship between the cluster model and the shell model and it is shown that in many cases the predictions of these two models are very similar.

This book can be strongly recommended. The reactions are considered from a theoretical point of view, but the results are extensively compared with the experimental data. The underlying physics of the nuclear model or nuclear reaction is kept continually in mind and the calculations made using simple models so that the physical principles are not obscured by mathematical or computational complexities. The book is likely to be of considerable interest to the nuclear physicist studying nuclear reactions at lower energies and to the physicist working with nucleons in the 100 to 400 MeV energy region. It is particularly valuable at a time when there is considerable interest in the use of high-energy particles to study nuclear structure.

C. J. BATTY

ERDTMAN'S PALYNOLOGY

Pollen and Spore Morphology/Plant Taxonomy—Gymnospermae, Bryophyta (Text)

By G. Erdtman. (An Introduction to Palynology, III.) Pp. 191+24 plates. (Stockholm: Almqvist and Wiksell, 1965.) 88 Sw. kr.

Pollen and Spore Morphology/Plant Taxonomy is the most recent volume of Prof. Erdtman's impressive series of contributions to the studies of spores and pollen of living plants. The rather disconcerting companionship of Bryophytes and Gymnosperms in the one volume is a reminder that palynology is still suffering the pains of over-rapid growth. The series (*An Introduction to Palynology*)

started bravely with Part 1, the Angiosperms, in a single volume of text and illustrations in 1952. Gymnosperms, Pteridophytes and Bryophytes (Part 2)—the illustrations only—followed in 1957. The present Part 3 is the text to the Gymnosperms and Bryophytes—the text for the Pteridophytes is still to come. This seemingly rather confused situation simply reflects the dilemma of the integrator in a field where research is outpacing the integration: Prof. Erdtman has elected "for various reasons" to postpone a description of Pteridophyte spores to a later volume.

But the present work is much more than merely a text to a volume of illustrations. It carries an additional twenty-four plates, and numerous half-tone illustrations in the text. These are of the usual excellent quality which has become the hallmark of Erdtman and his students at Solna. They include ordinary-light micrographs of acetolysed spores in distilled water; electron micrographs of shadowed replicas, to show exine topography; and thin sections of exine taken with phase contrast and ultra-violet. The refinement of technique in illustration since Volume 1 is a tribute to the painstaking application to the problems of spore illustration made by Prof. Erdtman and his students.

The body of the work is a description in catalogue form of spore and pollen morphology with the original figures of Volume 2 greatly augmented by new photographs. In every genus there are detailed references to the specimens examined and to the relevant literature. Occasionally, one regrets that Prof. Erdtman's enthusiasm for a logical and consistent terminology has taken us far from terms already well entrenched in 1957. Under his 'N.P.C.' system the monolete proximal aperture of a moss spore now falls into the same 'character' category as the (distal) colpus of, say, a cycad. As a result, some may be sorry to see the proximal aperture of *Splachnum* (katalept) referred to as a 'colpus' (with or without inverted commas!)—the same term being applied to the distal 'furrow' of cycad pollen.

There are two areas which show up in the book as being particularly in need of further work. First, our knowledge of the megaspore membrane within the seed of the gymnosperms and its structure and homologies with the microspore exine is sparse. (The megaspores occupy four pages, the pollen seventy.) Secondly, there is still lack of knowledge of orientation with respect to the tetrad in some pollen and spore types; even in such a large and well-studied genus as *Ephedra*, for example, there is controversy as to whether the elongated axis is polar or equatorial. Since any comparative pollen morphology must be based on the basic orientation of the spore, this is a feature of fundamental significance.

This work is a valuable contribution to the various fields of botany through which palynology ramifies—Quaternary palaeobotany, gymnosperm and bryophyte systematics and the more refined study of cell wall formation in general. There can be no greater praise of the book than to say that Prof. Erdtman has maintained the high standard of illustration, meticulous observation and description that he set in his own earlier work.

W. G. CHALONER

THE SIPHONOPHORA

A Synopsis of the Siphonophora

By A. K. Totton, assisted by H. E. Bargmann. Pp. vii + 230 + 40 plates. (London: British Museum (Natural History), 1965.) 220*s*.

SOME animal groups are easier to describe and classify than others, especially when creatures have hard skeletal characters. The softer-bodied animals have, however, given great trouble and, among these, the planktonic siphonophores are extreme examples. Not only are they liable to crumple and distort on preservation, but they consist of polymorphic colonies carrying floats, swimming organs, stomachs, stinging tentacles, sexual and asexual bells. Any one of these parts is liable to break off and a preserved collection may consist of fragments belonging to a number of different species. It is no wonder that the early systematists got into a muddle and different parts were assigned to wrong parent species. Even to-day many species are known only from fragments and the complete animals still remain to be described. But their beauty and strangeness have attracted the most famous zoologists, among the first to write large works on them being T. H. Huxley and Ernst Haeckel. In more modern times, however, the leader in the field was undoubtedly Henry B. Bigelow, who produced a classical work in 1911 based on the fine collections of the *Albatross*, to be followed by a number of subsequent reports.

Now we have before us *A Synopsis of the Siphonophora*. The author is A. K. Totton, whose first published work on siphonophores was in 1932 when he reported on the collections of the Great Barrier Reef Expedition. Totton, who was on the staff of the British Museum (Natural History), has had the unrivalled collections of the *Discovery* investigations at his disposal, but he has never been content to examine preserved material and, as a true naturalist, has spent much time in the field studying the living animal and its development, more especially at Villefranche, where upwelling at times brings rare species to the surface.

A quick perusal of his synopsis shows at once the leading position that Totton himself has earned in the study of this difficult group. He states that about one hundred and thirty certain species are now known. A check on the identity of these species shows that twenty-five can be attributed to Totton, who has thus named more than twice as many species as any other author, Bigelow coming second with eleven. Out of one hundred and fifty-three text-figures, some one hundred and twenty are Totton's own drawings, and of the forty plates twelve include original photographs by him.

The synopsis is not a comprehensive monograph. It lacks much information on general biology, on histology and geographical distribution, as Totton himself admits. Some of the species descriptions are indeed also somewhat cursory, and full synonymy lists are not given under the species. Synonyms should also have been included in the index. The possibilities of writing full-scale monographs such as A. G. Mayer's *The Medusae of the World* are growing less. It is all a matter of time. It is only those who have given many years to a study of a group who are competent to undertake the task and the coverage of the literature grows ever more time-consuming.

It is, however, becoming very essential that those with the knowledge should gather it together and make it available for those who follow. It is certain that in some groups, in which there is confusion in synonymy and of which the specific descriptions are scattered through a wide range of publications, young workers are deterred from entering the field. The publication of a comprehensive work always seems to produce a quick response of new workers.

The phylogeny of the siphonophores has always intrigued zoologists, and among these Walter Garstang was pre-eminent. In his introductory pages, Totton has given an informative review of the work and ideas of the most prominent investigators of the past. Included on the title page is the name of Dr. Helene E. Bargmann, the value of whose assistance can well be appreciated in putting together a work of this nature. Among the many attractions of the *Synopsis* are the reproduction in the plates of so many of the illustrations of the earlier naturalists and the amusing frontispiece.

The whole volume is splendidly produced and should long remain a standard work and an encouragement for the recruitment of future investigators. F. S. RUSSELL

Elementary Analysis

By Richard F. McCoart, Malcolm W. Oliphant and Anne E. Scheerer. (Holden-Day Series in Mathematics.) Pp. xv+251. (San Francisco and London: Holden-Day, Inc., 1964.) 7.95 dollars.

THIS book consists of a careful introductory course to differential and integral calculus. It is intended for a first-year course at a U.S. university and would be useful to sixth forms in Britain and to some extent to first-year students at a university doing a rather pure mathematical ancillary course. Subjects treated include the concept of functions, the ε–δ definition of limit, continuity, and introduction to the derivative and the Riemann integral by way of the concept of bounds. None of these subjects is developed very far, but so far as it goes the treatment is clear, careful and unhurried. There are plenty of exercises with answers supplied and some worked examples. R. L. PERRY

Slow Neutrons

By V. F. Turchin. Translated from the Russian. Pp. vi+304. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1965.) 107*s*.

THIS book is to be welcomed, for the field of neutron scattering is as yet not easily accessible except through original papers. At the time of its publication in Russian (1963) the book was the only one to treat thoroughly dynamic, inelastic scattering processes; this translation of it is likely to remain a valuable text for many years even though some other books are now available.

Turchin covers the basic neutron-scattering processes from individual nuclei and from condensed systems. He presents the theory necessary for the interpretation of elastic (Bragg) diffraction from crystals, and inelastic scattering both from crystals and from disordered (liquid-like) systems. This latter topic is thoroughly treated by the space–time correlation method.

The sections devoted to the various approximations useful for realistic situations are likely to prove particularly valuable to workers in the field. The section on magnetic scattering is short, but adequate. The second part of the book is entitled "Thermalisation and Diffusion of Neutrons" and discusses briefly the nature of these processes and their significance in reactor calculations. There are many existing better sources for this work, and in general a reader would do well to treat these chapters as introductory.

The standard of translation is high, but the formulae are badly set and difficult to read; the only error that I found, however, was the retention of Russian subscripts in one formula. The direct reproduction from typescript necessarily gives a slightly untidy appearance to the page, but a little more attention to the quality of the mathematical formulae and diagrams would have made the book far more pleasant to read. W. M. LOMER

General Genetics

By Adrian M. Srb, Ray D. Owen and Robert S. Edgar. Second edition. (A Series of Books in Biology.) Pp. xi+557. (San Francisco and London: W. H. Freeman and Company, 1965.) 50*s*.

THIS substantially revised, second edition of a most valuable text-book appears thirteen years after the first edition of 1952. The two original authors have been fortunate in securing the collaboration of a third, Dr. R. S. Edgar, a distinguished representative of the new generation of geneticists who, in his work with bacteriophage, has opened a new approach to physiological genetics at the molecular level.

Many things have happened since 1952; they are incorporated in this new edition. Just about that time fine genetic analysis was forcing a replacement of the concept of genes as beads on a string by that of words in a sentence, with each word coding for a protein. Soon afterwards the Watson–Crick model of DNA gave precise chemical meaning to this picture and suggested the way in which genes are replicated and the colinearity of the fine structure of a gene with the amino-acid sequence of a polypeptide. It took only a few years to confirm the former, but more than ten years to confirm the latter.

Thanks to these early developments and the many others, too well known to need mentioning, on the genetic code and protein synthesis, the biochemical and the genetical approaches to heredity, differentiation, development and evolution have become completely interwoven. Demarcation disputes, unfortunately still rampant, are becoming boring. This book may well help to bury them for good.

There are a few minor errors, such as the legend to Fig. 3·1, on page 67. The treatment of human genetics (Chapter 15) is inadequate and not up to date; better to omit it or treat the subject more significantly. Apart from these minor faults, there is little doubt that this new edition will, as its predecessor, secure many years of deserved success as an introductory text-book of genetics.

G. PONTECORVO

Research in Pesticides

Edited by C. O. Chichester. (Proceedings of the Conference on Research Needs and Approaches to the Use of Agricultural Chemicals from a Public Health Viewpoint, held at the University of California, Davis, October 1–3, 1964.) Pp. xx+380. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.) 128*s*.

SINCE the publication of Miss Rachel Carson's book *Silent Spring* in 1962, more words must have been spoken and written about pesticides, and the hazards of their residues in foods or of environmental contamination, than about any other aspect of applied biology. *Research in Pesticides* offers an up-to-date review of the present position on pesticides, not agricultural chemicals as stated in the sub-title, with the exception of legislative control.

At the conference reported in this volume, twenty-six specialists read papers covering a great diversity of aspects of pesticide usage in relation to public health. These aspects, according to the titles of the seven parts into which the conference was divided, cover criteria for public policy in the use of pesticides; approaches in the investigation of pesticidal action (on the pest); whole animal responses to pesticides; ecological systems (fresh water, land drainage, sea water, wildlife, domestic animals, plants); removal or persistence of pesticides (public water, air, soils, foods); alternate methods of pest control; and interpretation of data with respect to human health. Each aspect was covered by two to six papers, followed by one to three formal contributions to a discussion, but on only three occasions was there open discussion from the floor. There is a short, but helpful, topical index.

The great majority of the papers reach a high standard of summary and review, but most authors seem to have been unable to see further ahead than the clear need to amass more data. However, I particularly liked the contributions by O'Brien on target enzymes, Frawley on synergism, Freed on control of plants, Crosby on the international removal of residues, McNew on regulating the interaction of pest and host, and that portion of the open discussion to Part 7 commenting on the interpretation of animal in relation to human toxicology.

The standard of editing is high, but on pp. 52–55 appear three mentions of a contribution on pitfalls in studies of metabolism by Dr. Casida, who was in the audience. No explanation is offered for the omission from print of what seems to have been a very interesting paper. The book will clearly be an excellent reference volume for libraries, but those workers who would find a personal copy valuable, because of their need to take a broad view of pesticides in committee work or scientific administration, may be deterred by the price. E. A. PARKIN

MEETINGS

COSPAR — VIENNA, 1966

THE ninth Plenary Session of Cospar and the eighth International Space Science Symposium was held at the Congress Hall of the New Hofberg, Vienna, Austria, during May 10–19, 1966. Some 600 delegates and scientists from 33 countries attended. Three special topical symposia were held on life sciences and space research, the Moon and planets, and interactions between the neutral part and the ionized part of the atmosphere

Maurice Roy, representative of the International Union of Theoretical and Applied Mechanics, was elected to a second three-year term as president. The Bureau of Cospar is now composed of A. A. Blagonravov (Academy of Sciences, U.S.S.R.) and R. W. Porter (National Academy of Sciences, United States) as vice-presidents, with L. Egyed (Hungarian Academy of Sciences), K. Lauter (German Academy of Sciences at Berlin), Sir Harrie Massey (Royal Society of London), and M. Nicolet (Royal Academy of Sciences of Belgium). The tenth meeting of Cospar will take place during July 17–28, 1967, in London; the first week will be a joint session with the fourth General Assembly of the IQSY, and the special symposium at the meeting will be about the scientific results of that programme.

Working Group I—Tracking, Telemetry and Dynamics. Concern was expressed over the need to protect certain radio frequencies used for tracking satellites and for receiving beacon and telemetry signals. It is difficult to assign a protected frequency to satellite transmitters, for the regulations of the International Telecommunications Union require that in such a case an identifying call name must be assigned This is usually impractical, because satellite transmissions often contain only the telemetry channels for command and data relay. Some satellites continuously broadcast data through telemetry channels, often so as to relate satellite data directly with data obtained from the ground simultaneously. These telemetry emissions also require protection. These matters are to be discussed further with representatives of the International Radio Consultative Committee, and formal requests for frequency allocations will be filed through channels to the International Telecommunications Union.

Optical means of tracking satellites range from accurate astronomical telescopes of the Baker–Nunn type and others to observations made with an ordinary press camera with a 4 in. × 5 in. negative. The latter has proved effective in filling in orbit information, especially during the early days of a satellite before accurate prediction ephemerides are available to guide the narrow field astronomical instruments. Visual observations by skilled teams are also of considerable importance in the early and late phases of an orbit. Recent work by King-Hele indicates the usefulness of skilful camera and visual observation in determining atmospheric drag—and hence deducing atmospheric density—especially for low-perigee satellites. The Working Group urged continued attention by amateur groups to good observation, especially in the Southern Hemisphere, and urged that coverage should be increased.

The Working Group also agreed to study the possibility of distributing listed observations in a form directly accessible to machines. The need was pointed out for the determination of position and proper motion of stars in the southern half of the celestial sphere, so that better optical tracking can be achieved in the Southern Hemisphere. Support for the efforts of the International Astronomical Union to compile a southern hemisphere star atlas was also recommended.

Mrs. Alla Massevitch (U.S.S.R.), who has chaired this Working Group since the inception of Cospar, resigned. J. Kovalevsky (France) is the new chairman and D. J. King-Hele (U.K.) vice-chairman.

Working Group II—Design and Co-ordination of Experiments. One of the important programmes discussed by the panel on the dynamics and structure of the neutral atmosphere was the sounding of the atmosphere above balloon ceilings by small meteorological rockets. Some four thousand soundings are now available, chiefly from the United States network of some fifteen stations, but regular firings are also conducted by the U.K. Meteorological Office at South Uist in the Hebrides, and rockets have been fired from India, Pakistan, Australia, France, Italy, Iceland, Norway, Sweden, Spain, Poland, Egypt, Israel, U.S.S.R., Argentina and Brazil. German groups have fired rockets from various locations outside the Continent; the Japanese are testing rockets in preparation for regular firings in a year or so, and interest has been expressed by Canada, Greece and Columbia. Rockets have been fired at McMurdo Sound, Antarctica, and at Thule, Greenland, and from ships. In a few years, a world-wide network of meteorological rockets may be a distinct possibility. Regional groups have been organized for the Indian Ocean and the Americas. The panel strongly endorsed these efforts, and hoped that such groups could become the mainspring for an effort to obtain good latitude coverage along particular meridians, and urged that additional groups should evolve, particularly in Europe and in the Western Pacific and East Asian Regions. A latitude profile based on observations from two ships in the western Pacific undertaken by the U.S.S.R. attracted interest, and it was suggested that such efforts be coordinated into land-based latitude chains.

Because of the wide interest in data from the rapidly evolving network of rocket stations, among ionospheric physicists as well as meteorologists, an effort has been made in the past year to centralize the collection and publication of rocket profiles. World Data Center *A* for Meteorology (United States) has agreed to publish data on a month-by-month basis, and the first volume (for July 1965) was distributed. Countries obtaining rocket meteorological data are now urged to submit data to the World Data Center for meteorology within 4 weeks of a firing for inclusion in the appropriate volume due to appear after a delay of 6 months.

The importance of dust in the solar system and the upper atmosphere of the Earth was discussed by an *ad hoc* group, which suggested that a formal Cospar panel should be organized on this subject. This suggestion will be considered at the London meeting following a scientific symposium on dust to be arranged by the *ad hoc* group, whose goals would then be further clarified.

The Working Group also turned its attention to experiments or programmes that would benefit from coordination on a multilateral or global basis, with particular attention to the period of solar maximum a few years hence.

Working Group III—Data and Publications. The desirability was again emphasized that launching groups should supply descriptive summaries of rocket flights, giving brief information on the experiments, and similar summaries for satellites and space probes. In order to simplify the mechanics of distributing data on satellite launchings, it was decided to use telecommunications only for those satellites with which speed is essential, as, for example, when real-time telemetry is employed, or where the spacecraft is of optical or radio interest (flashing lights, radio beacons, etc.).

Working Group IV—International Reference Atmosphere. Support was added to the request of other working groups for more data in the region between balloon ceilings (30–40 km) and satellite level (several hundred km) and particularly for data from meteorological rockets on the upper stratosphere and mesosphere, and data on density and temperature in the region of 150–200 km by the tracking of low-altitude satellites. Interest was also expressed in attempts to take account of essentially regular dynamical effects, such as the solar heating bulge in the upper atmosphere and the solar tidal motion in the middle atmosphere which is now regarded as a consequence of solar heating in the ozonosphere and not a resonant response to the gravitational tide. Interest was also expressed in an attempt to develop a reference ionosphere. These two topics, and particularly the latter, are complex and it is probably premature to make decisions on these elaborations of the reference atmosphere.

Luigi Jacchia (United States) was elected chairman of the Working Group to succeed Dr. W. Priester (West Germany), and V. I. Krassovsky (U.S.S.R.) vice-chairman.

Working Group V—Space Biology. The question of space probe sterilization received considered attention, with an exchange of information on techniques now in use in the U.S.S.R. and the United States and some plans for future probes. A conference on space-probe sterilization was planned as a prelude to the London meeting. There will also be a two-day symposium at this meeting, covering areas such as the biology of the inner planets, strategy and tactics of life-detection schemes, orbiting biological experiments, and long-term effects of weightlessness on the cardiovascular system.

Working Group VI—Scientific Space Experiments concerned with the Properties and Dynamics of the Troposphere and Stratosphere. The terms of reference of this Working Group, established at the meeting last year in Argentina, imply support for the interest of the International Council of Scientific Unions and the World Meteorological Organization in developing a world-wide system of meteorological observations. It is therefore mainly concerned with determining atmospheric parameters over the globe through indirect techniques of electromagnetic sounding and atmospheric probes (constant-level balloons) and at the surface (remote astromatic station, ocean buoys) located by satellite ranging systems.

The Working Group agreed to prepare a document on (i) the specification of a global meteorological experiment; (ii) the design of experiments to test atmospheric predictability; (iii) the design of experiments to study the spectral distribution of atmospheric energy μ, a function of the scale size of disturbances; (iv) the status of the art of indirect probing and a look to the future for such parameters as temperature, density, pressure, wind, surface state, cloud, radiation flux, water vapour and ozone; and (v) a status report on the constant-level balloon systems now under test (GHOST balloons, United States) and development (by the EOLE group in France), and on the satellite ranging and interrogation schemes which are under development

Popular Education and Training. A panel with this title was organized in response to the United Nations request to the scientific unions for advice on ways in which space science could be used to accelerate technical training and education in developing countries. The panel suggested that the use of certain geodetic satellites for accurate surveying in Africa shows how this kind of work may be a good possibility for many developing countries. Another possibility is the improvement of local weather services by means of automatic equipment taking pictures from the TIROS satellites. Many such units have been built in universities, and it was considered that such developments are not in principle beyond the reach of universities in developing countries.

STANLEY RUTTENBERG

OBITUARIES

G. R. Crowe

A COLLEAGUE writes:

G. R. Crowe, who died in June aged 73, spent most of his working life in the Cavendish Laboratory. Starting as a boy in 1907, and leaving the Laboratory only during the First World War when he worked at the Cambridge Instrument Company, he retired as principal assistant in 1959. To a few he was "Crowe", but to most of us he was "George".

Crowe became Rutherford's personal assistant in 1919, a post which he held until Rutherford's death in 1937. Throughout this period many of Rutherford's best experiments owed much to Crowe's skill and perseverance. Essentially he was a man with good hands who was skilled in most of the contemporary laboratory techniques. He could do most things that required to be done whether it was with metal or glass or photography. With such old-fashioned things as wax or mica he was an artist. Perhaps his greatest single contribution to Rutherford's work was the preparation of the thin glass tubes in which radioactive emanation was sealed. It would still be an exercise for an apprentice to make the tubes. When one adds the difficulty and the hazards of the radioactive filling it was a task for a craftsman.

One of the greatest delights in the 1930's for Rutherford and Crowe were the Royal Institution lectures. For both of them the lectures were at once a challenge and a holiday. It is doubtful whether Rutherford ever spent so much time preparing a set of lectures, and much of the work of the Laboratory came to a halt until the preparations were complete. The master's ideas were shaped and made practicable by Oliphant and Wynn Williams, but the detailed execution fell largely to Crowe. It was not trivial in 1934 to build a portable Cockcroft and Walton accelerator with subsidiary counting equipment and to erect it in London on a "one-night stand" and therewith to give the first public demonstration of nuclear transmutation. This, of course, was a laboratory effort, but Crowe did his part, a very large part, supremely well.

The "If's" of history are many. Not the least interesting to a physicist is the speculation as to how much, or how little, some of the eminent would have achieved without skilled assistants. Whittaker, in his *History of the Aether*, records of Oersted that he was "a man of genius but a very unhappy experimenter: he could not manipulate instruments". On the other hand, we can be quite certain that the president of the Royal Society in 1966 would still have been president if laboratory assistants had never existed. Crowe's opinions on this subject were interesting and emphatic. When he entered the Cavendish as a boy, J. J. Thomson was the Cavendish professor. From his own observation supported by gossip with Everett, Thomson's assistant, Crowe concluded that J. J. was never allowed to touch any apparatus whatsoever—otherwise disaster inevitably followed. Of his own master, Rutherford, Crowe had many colourful stories, many of them bearing on this subject. The tenor of them can be summarized in the Rutherford exclamation, "Don't shake the bloody bench, Crowe", when the great man was patently failing with something which required manipulative dexterity. Although, in this case, Crowe was the only witness—as well as judge and jury—there is little reason to doubt the substantial correctness of his comments.

In his prime, a man of considerable physical strength and an enthusiastic player in the Cavendish cricket match, Crowe was endowed with a calm temperament and was not easily ruffled. He allowed the sometimes violent storms, of which Rutherford was the sole and only origin, to pass over him. In this he was assisted by his partial deafness. It was always very difficult for Rutherford in

one of his tempers to know whether Crowe could not or would not hear him.

It was natural that Bragg should turn to Crowe for help in the preparation of his own Royal Institution lectures when he succeeded Rutherford in the Cavendish chair. These lectures were distinguished by a quite exceptional clarity and thoroughness of preparation and owed a great deal to Crowe's patience and skill in mastering extremely ingenious and delicate techniques. It was not only in this work, however, that Bragg found Crowe's practical skill a match for his own inventiveness. They worked together during the Second World War, and almost immediately afterwards Crowe ventured into a new field, assembling and operating the first electron microscope in the Laboratory, one of the first in the country. Even Crowe's temperament was stretched to the limit by this wayward instrument and he always maintained it was during this period he learnt to swear "aloud". Nevertheless, Bragg's wisdom in setting Crowe to the task bore rich dividends in Crowe's contributions to the technique of preparing specimen replicas.

In the Cavendish, Crowe was respected for what he could do and well liked for what he was. In experimental physics his death marks the end of an era. No one now in pursuit of the highest prizes plays with wax or bothers to split mica. Yet these trivialities played a not negligible part in an intellectual revolution. It is right that the man who could do them and did them should be remembered.

Prof. J. M. Mackintosh

PROF. J. M. MACKINTOSH died at his home in Bristol on April 20, at the age of 75. In his lifetime he spanned almost the whole of our experience of public health, first as County Medical Officer of Northamptonshire, then as Chief Medical Officer of the Department of Health for Scotland, professor of public health at Glasgow, and as dean and professor of public health at the London School of Hygiene and Tropical Medicine. A highlander by origin and temperament, he was born in Kilmarnock where his father practised as a solicitor, and educated at Glasgow High School and University. He was a graduate in arts and medicine in the older Scottish tradition of the educated doctor: at the University of Glasgow he was one of a vintage generation whose studies were interrupted by active service in the First World War. Severely wounded as a subaltern in the Cameron Highlanders, he was sent home and finished his medical studies. He returned to the war as a medical officer in the R.A.M.C. It was war-time service which determined his choice of public health as a career.

After service as an assistant medical officer in Dorset, Burton-on-Trent, and Leicestershire he was appointed County Medical Officer of Northamptonshire in 1930. There he made a celebrated series of surveys of rural housing, and his reports, illustrated with his own pen-and-ink sketches, are a unique piece of English social history. He loved his period of public health service.

From 1937 until 1941 he served as Chief Medical Officer of Scotland This was a period when attention had turned in Scotland to the need for major reform of the health services, and a period of hectic planning in anticipation of war. This experience was formative of his thinking about hospital planning and strategy At this time, too, James Mackintosh discovered with a special delight and appreciation the Highlands and Islands Medical Service which had pioneered the provision of health services for remote and scattered populations; in retirement it was one of his unrealized hopes that he might be able to write a history of the service.

In 1941 he resigned from central government work, which he had felt restricting and lacking in those individual contacts whose stimulus he found rewarding. He moved to the chair of public health of the University of Glasgow and began the academic career by means of which his name has become widely known. To begin with, however, he was still concerned with war and was moved to the United States to advise on the medical aspects of civil defence. This was the beginning of an association with American colleagues which continued for the rest of his life. In 1944 James Mackintosh was appointed dean and professor of public health at the London School of Hygiene and Tropical Medicine and continued there until his retirement in 1956. The end of the war was a time of ferment. Young men out of the forces were eager to make their mark in their country's health services. Increasingly, postgraduate students came to learn from British experience and teaching. The times welcomed the gifts of James Mackintosh as a thinker and teacher. His lectures on the history and development of health services were a delight, tantalizing to those who wanted a text-book exposition, but profoundly educative in giving a sense of historical perspective and the development of health services as a function of contemporary culture and thought. Mackintosh was beyond all else a social philosopher of the health services, weaving his text from wide reading and experience, and illuminating generalizations from the particular example with a special skill of his own.

When he retired from his chair in 1956 he was already frail and in poor health. He nevertheless had two further successful careers before he died. He worked in Geneva as a consultant to the World Health Organization, and was largely responsible for the production of its *First Report on the World Health Situation*, a classic of its kind. He later worked in the United States for the American Hospital Association and the Milbank Foundation, and his volume of essays on *Topics in Public Health* published last year was partly produced at that time.

J. H. F BROTHERSTON

Dr. A. C. Stephen

DR. ALEXANDER (ALASTAIR) CHARLES STEPHEN, who was keeper of the Department of Natural History in the Royal Scottish Museum from 1935 until 1958, died suddenly at his home in Edinburgh on June 3 at the age of seventy-two.

Born at Garvock, Kincardineshire, he was educated at Robert Gordon's College and Marischal College, Aberdeen. His academic course was interrupted by service in France and Belgium, but he graduated at Aberdeen in 1919. His first appointment was junior naturalist on the scientific staff of the Fisheries Board for Scotland in 1920, where he was responsible for an investigation into the distribution of animal life on the bottom of the North Sea and adjoining areas.

He joined the Royal Scottish Museum in June 1925 as assistant in the Department of Natural History, and his period of service was notable for the opening of new halls and galleries which, in their presentation of material, were well in advance of other museums in Britain. He continued his research in marine zoology and was the first to apply techniques for quantitative study to the intertidal fauna of sandy and silty shores—work which yielded valuable information on the ecology of these zones and formed his thesis for the D.Sc. in 1934. He wrote on the distribution of cephalopods in British waters and was an authority on the taxonomy of echiurids, sipunculids and priapulids, publishing several reports on material from Africa collected during the *Discovery* and John Murray Expeditions, and from the B.A.N.Z.A.R. Expeditions. He completed a synopsis of the British species and, at the time of his death, was engaged in the preparation of a monograph of the world species.

For many years he was editor of the *Scottish Naturalist*, and he served also as president of the Royal Physical Society of Edinburgh and the Astronomical Society of Edinburgh. He was also a Fellow of the Royal Society of Edinburgh.

INTERSTELLAR VEHICLE PROPELLED BY TERRESTRIAL LASER BEAM

By PROF. G. MARX
Institute of Theoretical Physics, Roland Eötvös University, Budapest

THE extreme difficulties of interstellar space travel are well known[1]. It is a commonly accepted view that, apart from the technical difficulties involved, the laws of conservation of energy and momentum forbid the visiting of other planetary systems in the human life-span[1]. This article sets out to show that this is not necessarily the case. To arrive at the nearest stars in the life-span of the astronaut a relativistic velocity is needed. The kinetic energy, K, of vehicle of rest mass, M, moving at the velocity $c\beta$ is:

$$K = Mc^2\left(\frac{1}{\sqrt{1-\beta^2}} - 1\right)$$

Here c is the velocity of light. To achieve a relativistic velocity the vehicle would need to have a propellent energy, W, that greatly exceeds the most optimistic estimates of the technical possibilities in the foreseeable future. The reason for this is the very low mechanical efficiency of rocket propulsion in the relativistic domain[2]. A rocket can be accelerated only by the reaction of its exhaust gases. The greater part of the energy liberated from the propellant is lost in the form of the unavoidable recoil motion of the small masses of the exhausted gas particles. This is a direct consequence of the conservation of energy and momentum. To prevent wastage of energy, the only possibility seems to be to transfer the recoil momentum to the Earth. Because of the large mass of the Earth, its associated recoil energy is negligible, as in the case of a car, running on a solid road. As a possible realization of this principle, consider the following propulsion system: a departing vehicle has an effective cross-sectional area, f, as seen from the Earth, and acts as a perfect reflector of light in the backward direction. A light beam of constant intensity, I, coming from a terrestrial light source, is reflected by it. If the vehicle moves with the speed $c\beta$, the intensity of the reflected light, I', turns out to be smaller than I. The momentum gained by the vehicle is $c^{-1}f(I+I')\mathrm{d}t$, and the energy gained is $f(I-I')\mathrm{d}t$ during the time interval $\mathrm{d}t$, and the vehicle is accelerated from the velocity $c\beta$ to $c(\beta+\mathrm{d}\beta)$.

The equations expressing momentum and energy conservation are:

$$\frac{If}{c^2}c\,\mathrm{d}t + \frac{Mv}{\sqrt{1-\beta^2}} = \frac{M(v+\mathrm{d}v)}{\sqrt{1-(\beta+\mathrm{d}\beta)^2}} - \frac{I'f}{c^2}c\,\mathrm{d}t$$

$$If\,\mathrm{d}t + \frac{Mc^2}{\sqrt{1-\beta^2}} = \frac{Mc^2}{\sqrt{1-(\beta+\mathrm{d}\beta)^2}} + I'f\,\mathrm{d}t$$

These can also be written as differential equations of the motion:

$$I + I' = \frac{Mc^2}{f}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\beta}{\sqrt{1-\beta^2}}\right)$$

$$I - I' = \frac{Mc^2}{f}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{1}{\sqrt{1-\beta^2}}\right)$$

Adding and subtracting these equations give:

$$I = \frac{Mc^2}{2f}\frac{\mathrm{d}}{\mathrm{d}t}\left(\sqrt{\frac{1+\beta}{1-\beta}}\right) \qquad (1)$$

$$I' = -\frac{Mc^2}{2f}\frac{\mathrm{d}}{\mathrm{d}t}\left(\sqrt{\frac{1-\beta}{1+\beta}}\right) \qquad (2)$$

If the incoming intensity, I, is constant in time, then, by integration, the terminal velocity:

$$\frac{v}{c} = \beta = \frac{(1+2\tau)^2-1}{(1+2\tau)^2+1} \qquad (\beta = 0, \text{ if } \tau = 0) \qquad (3)$$

Here τ is the ratio of the radiant energy, W, used up during the time t, to the rest energy of the vehicle:

$$\tau = \frac{Ift}{Mc^2} \equiv \frac{W}{Mc^2}$$

Substituting equation (3) back into equation (2), the following expression for the "instantaneous mechanical efficiency" is obtained:

$$\eta_m = \frac{\mathrm{d}K}{\mathrm{d}W} = \frac{I-I'}{I} = 1 - (1+2\tau)^{-2}$$

If $\tau \to \infty$, that is, if $v \to c$, the instantaneous efficiency rises up to 100 per cent; almost the whole energy of the light falling on the mirror is converted into the kinetic energy of the vehicle in the extreme relativistic limit.

The "total mechanical efficiency" can be defined as a ratio of the kinetic energy of the vehicle (starting from rest) to the radiant energy of the beam incident on it:

$$\eta_t = \frac{K}{W} = \frac{1}{1+(2\tau)^{-1}}$$

The total efficiency starts from a very low value (valid for non-relativistic motion) and rises to 100 per cent when the vehicle has reached relativistic velocity. It can thus be seen that, with "a solid ground below the feet", all the principal difficulties of interstellar space flight disappear. A vehicle can be accelerated almost to the speed of light if an emitter on the Earth can accurately project light on to its mirror.

To make this technically possible, an ideal focusing is needed. All light sources emitting natural light must be excluded because of the divergence of the small wave pockets. The only possibility is offered by the coherent radiation of the laser. If the divergence angle of the laser beam is taken as:

$$\alpha = \mathrm{tg}^{-1}(\lambda/\rho)$$

where λ is the wave-length and ρ is the radius of the coherently radiating surface of the laser, then the maximum range of operation, r, may be estimated (in units of light years) as:

$$r = 0{\cdot}1\,a\,\rho\,\varepsilon$$

where a and ρ are the radii of the mirror and laser surface, respectively, both in the kilometres, and $\varepsilon = hc/\lambda$ is the energy of the light quanta in kiloelectron volts; h is Planck's constant. It can be seen that the technical conditions are extremely exacting. A range of operation of 0·1 light year would require a coherently radiating surface of the order of 1 km² which emits hard X-rays, and the vehicle would need an X-ray mirror with an effective cross-sectional area of several km².

As a matter of fact, this propulsion system would also operate without an ideal mirror. If the mirror were replaced by a black surface, and if the absorbed light

energy were radiated out isotropically into the space in the reference system of the vehicle, the instantaneous mechanical efficiency turns out to be:

$$\eta_m = \frac{dK}{dW} = \beta \frac{1+\beta}{1+\beta^2}$$

and thus:

$$\lim_{\beta \to 1} \eta_m = 1$$

In spite of this, the technical realization of these conditions would seem to be practically impossible in the next few decades. (But the construction of a photon rocket with 90 per cent mechanical efficiency is perhaps an even more difficult task.)

Laser propulsion from the Earth may be possible only in the very distant future. It would solve the problem of acceleration, but not the problem of deceleration on arrival at the destination. But if radio contact had been reached with intelligent beings on another planet, a man-carrying space-ship could start from the Earth, accelerated by our laser stations It could be accelerated up to 0·99c just after leaving the Earth and could then run with this speed through interstellar space. The receiving planet could then decelerate the vehicle to zero velocity. Travelling home could take place in the same manner.

No planet could be invaded in this fashion by unexpected visitors from outer space, which would perhaps explain why no real evidence of such invasions has been found on Earth up to now.

[1] Excellent summaries of the problem are given by Sheperd, L. A., *Realties of Space Travel* (London, Putnam, 1957); Hoerner, S V., *Science*, 137, 18 (1962); and Pierce, J. R , *Proc. Inst. Radio Eng.*, 47, 1053 (1959), where further references are to be found.

CO-OPERATIVE SCATTERING OF LASER LIGHT BY A THETATRON PLASMA

By D. E. EVANS, M. J. FORREST and J. KATZENSTEIN

Atomic Energy Research Establishment Culham Laboratory, Nr. Abingdon, Berkshire

It is now well known that the illumination of a plasma by a monochromatic uni-directional light beam results in a spectral distribution of scattered light the shape of which depends on the ratio, α, of the scale length for scattering to the plasma Debye length. It has been shown theoretically[1] that the spectrum can be regarded as the sum of two parts, first the electron feature which predominates when $\alpha \ll 1$ and has a Gaussian shape, and second, the ion feature which accounts for most of the scattered light when $\alpha \gg 1$. In the neighbourhood of $\alpha = 1$ the electron term is no longer Gaussian but begins to be depressed in the centre and to show some signs of resonances displaced from the centre frequency by $\pm \sqrt{2}\omega_p$, the plasma frequency. By the time α is 3 or 4 these resonances are well developed and the Gaussian character of the distribution has entirely vanished. Evidence for the deformation of the Gaussian electron feature near $\alpha = 1$ has been reported by Kunze *et al.*[2] and Ramsden and Davies[3], and more recently Chan and Nodwell[4] and Ramsden and Davies[5] have described the appearance of the plasma frequency resonance for higher α.

This article reports measurements of the distribution of light scattered into the electron feature in circumstances when α varied between 1·2 and 1·5. A Kerr-cell *Q*-switched ruby laser and amplifier provided 70-MW pulses within a divergence angle of 6·7 milliradians and these were used to illuminate the plasma produced by a 45 kJ (30 kV) theta pinch machine, *MAGGI* II. The experimental arrangement is shown in Fig. 1. Laser light is focused into a 6-mm diameter cylinder along the axis of the coil within which the plasma is formed, by the usual arrangement of lenses and stops, and is conveyed away through a 3-m long tube to a system of absorbers of blue glass (Chance *OB*10) chosen for its very low coefficient of surface scatter. Light scattered at 5° to the forward direction by a 10-cm length of plasma at the centre of the coil passes through an annular window concentric about the coil axis, then through an axicon from which it emerges parallel to the axis. This is followed by a silvered mirror which reflects the light through 90°, a lens of focal length 3 m, and in its focal plane a 5-cm aperture which defines the range of angles around 5°, namely ± 0·5°, into which light is accepted by the detector. The latter consists of a dielectric multilayer filter supplied by Thin Films Inc., and an RCA 7265 photomultiplier having a photocathode with an *S*20

Co-operative scattering of light in a θ-pinch plasma

Fig 1. Schematic diagram of the experimental layout

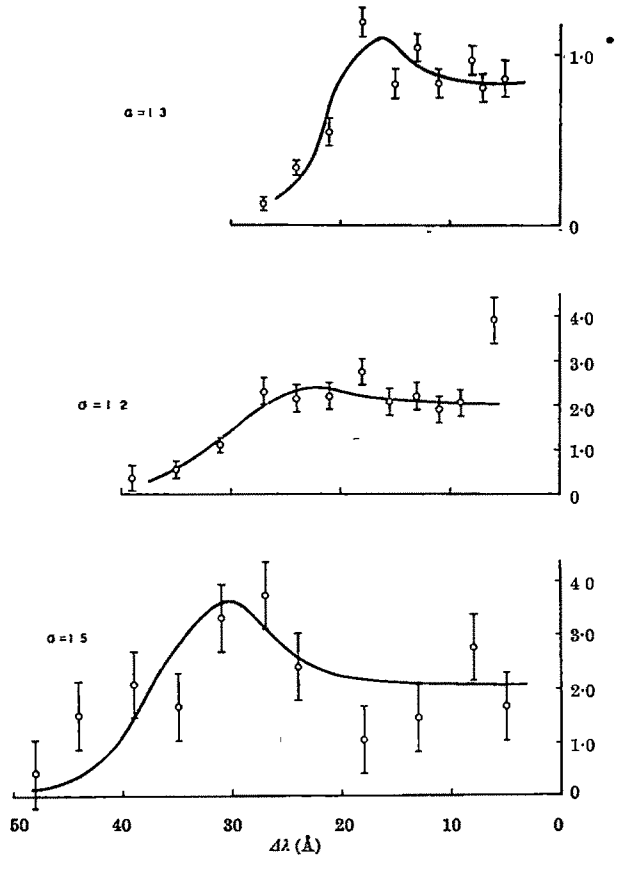

Fig. 2. Spectra of light scattered at 5°. Abscissa is the shift from the laser wave-length in Ångstrom units. Ordinates are arbitrary intensity units. Curves are best-fit theoretical scattered light functions

response. The filter is centred at 6943 Å and has a half-width of 5 Å when illuminated normally by monochromatic light reaching it through the system already described. Its pass-band shifts to shorter wave-lengths as it is tilted away from normal incidence, thus permitting its use as a spectral resolving instrument, though confining investigation of the spectrum to the blue side of the laser wave-length.

Spectral distributions of scattered light obtained under various machine operating conditions are presented in Fig. 2. They were built up from a series of individual shots—about a hundred shots being required to produce each spectrum. Each point represents the difference between the average of a set of shots with plasma, and that of a set without plasma at the same setting of the filter. The errors on the points are experimental in that they are derived from the root mean square deviation from the mean of the sets of experimental readings. Probable sources of the observed error are plasma light noise and fluctuations in the plasma parameters from shot to shot. Variations in the intensity of the laser output were detected by a photodiode monitor and were normalized out of scattered light signals. A residual fluctuation in the normalized stray light signals suggests an additional source of noise which has not been identified as yet. Stray light at the laser frequency was equivalent in intensity to that which would be produced by Rayleigh scattering on cold nitrogen gas at a pressure of about 160 torr, so that although scattered light could be detected at the centre of the spectra, it gave an enhancement over the stray light of only about 20 per cent. Nevertheless, the contrast of the filter was so high that beyond about 4 Å from the centre, scattered light was readily distinguished from stray.

To each set of experimental points a theoretical spectrum function of the form:

$$\Gamma_\alpha(x) = e^{-x^2}\{[1 + \alpha^2 - \alpha^2 f(x)]^2 + \pi\alpha^4 x^2 e^{-2x^2}\}^{-1}$$

where $f(x) = 2xe^{-x^2}\int_0^x e^{t^2}\,dt$ was fitted.

The abscissa was scaled according to the relation:

$$\frac{x}{x_s} = \frac{\Delta\lambda}{(\Delta\lambda)_s}$$

in which the subscript 's' refers to the value of x or $\Delta\lambda$, the wave-length shift, at the peak or shoulder of the function. It is of interest that where α lies between 1 and 2, $x_s \cong \alpha$ to better than 5 per cent, from which it follows that the position of the peak or shoulder depends only on plasma density. By a process of trial and error the value of α was determined to the nearest tenth, for example in the first of the spectra it became plain that $\alpha = 1{\cdot}3$ was a better fit than either 1·2 or 1·4. Similarly the position of the peak value, $(\Delta\lambda)_s$, was estimated to be correct to the nearest Ångstrom unit, since a change of 2 Å either way produced a readily detectable deterioration in the apparent goodness of fit.

The first two spectra were observed when the discharge tube was filled with hydrogen at a pressure of 20 mtorr, and 1 kG of reverse bias field was applied. A pre-ionizing pulse (110 J, 34 kV) ensured breakdown of the gas in the first half-cycle of the discharge of the main condenser bank. The first spectrum was measured half-way in time to the peak of the first half-cycle current pulse; the second was measured at the peak. The difference between the two is attributed to the change in the plasma properties as compression occurs. The best fit for the first spectrum was characterized by the parameters $\alpha = 1{\cdot}3 \pm 0{\cdot}05$ and $(\Delta\lambda)_s = 16$ Å $\pm$ 1 Å, from which electron density $n_e = \left(6{\cdot}0^{+1{\cdot}0}_{-0{\cdot}6}\right) \times 10^{15}$ cm^{-3} and electron temperature $T_e = 103^{+29}_{-17}$ eV were calculated. The second spectrum yielded $\alpha = 1{\cdot}2 \pm 0{\cdot}05$ and $(\Delta\lambda)_s = 22$ Å $\pm$ 1 Å, giving an electron density $n_e = \left(1{\cdot}16^{+0{\cdot}14}_{-0{\cdot}06}\right) \times 10^{16}$ cm^{-3} and electron temperature $T_e = 233^{+51}_{-28}$ eV.

The third distribution in the figure was measured at the peak of the first half-cycle of the current at a filling pressure of 50 mtorr of hydrogen and in the presence of 500 G of reverse bias field. The best fit in this case gave $\alpha = 1{\cdot}5 \pm 0{\cdot}05$ and $(\Delta\lambda)_s = 30$ Å $\pm$ 1 Å, corresponding to density $n_e = (2{\cdot}15 \pm 0{\cdot}15) \times 10^{16}$ cm^{-3}, and electron temperature $T_e = 278^{+40}_{-36}$ eV.

An independent measurement of the electron temperature in this plasma has been made under the same plasma conditions as those applying to the second of the three distributions in the figure by D. Beach *et al.*[6]. Their experiment, which also dealt with laser light scattering, was performed at 90° and so had an $\alpha \ll 1$. Their estimate of temperature is $T_e = 240 \pm 36$ eV, which agrees favourably with that measured by us.

We consider that the importance of these measurements lies in their application as a plasma diagnostic technique, for it is only when α is in the neighbourhood of 1 or 2 that measurements of T_e and n_e can both be derived from the spectrum of the scattered light without any knowledge of the absolute intensity.

We thank the Laser Group of the Atomic Weapons Research Establishment, who provided the laser, and Dr. J. A. Reynolds and Mr. J. A. Daniel for advice on and operating the thetatron.

ROLE OF AMMONIA IN THE ATMOSPHERIC CORROSION OF MILD STEEL

By Prof. T. K. ROSS and Dr. B. G. CALLAGHAN*
Department of Chemical Engineering, Faculty of Technology, University of Manchester

THE atmospheric corrosion of mild steel in Great Britain is associated with a high level of pollution, and sulphur dioxide in particular has received considerable attention as a predominant factor in atmospheric corrosion. Although some corrosion rates have been correlated with the sulphur dioxide level, anomalies do exist and this is considered to indicate that other pollutants may also be important.

As long ago as 1788 it was known that ammonia is one of the products of corrosion[1], and in recent years Ambler[2], Harrison and Tickle[3], and Young[4] have all investigated its presence in natural corrosion products.

The source of the ammonium ion found in such material has now been established and light thrown on its role in the corrosion process[5].

Examination of the rust formed on steel exposed to air in Manchester, as well as that formed in controlled laboratory atmospheres, has shown that the nitrogen content of the steel contributes mainly to the adherent inner rust, whereas atmospheric pollution contributes to the loose outer rust.

The seasonal variation in the total ammonia retained on a specimen exposed in Manchester is presented in Fig. 1; irrespective of when the specimen was first exposed, the ammonia retention rose in the winter months, falling again in summer. When the percentage of ammonia in the rust is plotted as in Fig. 2, it can be seen that the specimens of short exposure length exhibit a higher percentage of ammonia in the rust, as for example for specimens first exposed in September 1964 and February 1965. Furthermore, the ammonia is higher in the adherent rust in these early stages, but with prolonged exposure the ammonium content of the loose outer rust becomes predominant. Thus the seasonal variation in the amount of ammonia retained on a specimen follows a similar relationship to that noted for sulphates formed as a result of sulphur dioxide pollution. More significant, however, is the high ammonia content of the rust in the early stages of the corrosion process, particularly as it is associated with the adherent rust close to the metal surface.

To establish the role of the ammonium ion in the initial stages of corrosion, clean specimens of mild steel were subjected to a fine mist of atomized salt solutions for about 20 sec, and the effects of the salt solutions observed. The following solutions were atomized:

Salt solution (10 per cent w/v)	pH	Salt solution (10 per cent w/v)	pH
Sodium chloride	6·1	Ammonium chloride	5·2
Sodium sulphate	8·3	Ammonium sulphate	5·1
Sodium carbonate	11·0	Ammonium carbonate	9·2

Ammonium chloride and sulphate reacted more rapidly than the equivalent sodium salts, and also appeared to involve the entire surface of the specimen in the corrosion process. The attack in the presence of sodium ions was usually at discrete sites, and on drying salt nuclei were still discernible. Neither specimen contaminated with carbonates exhibited corrosion. The severe attack occasioned by ammonium salts may be due to the acidity of their solutions, but the observation that the attack in general affected the entire surface, giving it a 'wetted' appearance, was considered to be important.

The surface tensions of the solutions used were all greater than that of water[6], and would not therefore encourage wetting. However, once electro-chemical corrosion commences, hydroxyl ions are liberated at cathodic sites by the oxygen reduction reaction, and these ions together with the cation of the contaminant form the appropriate hydroxide. It would seem that it is the cathodic hydroxide that characterizes the corrosion process in the presence of the ammonium ion, for whereas sodium hydroxide solutions have a surface tension greater than that of water, that of ammonium hydroxide is lower. These properties are illustrated in Fig. 3, where the surface tension of water at 20° C is taken as an arbitrary zero, and surface tension-concentration profiles drawn. Thus, solutions possessing a negative surface tension with respect to water would preferentially wet a solid surface, while those with positive surface tensions would be non-wetting. The surface tensions of solutions of sodium chloride, sodium sulphate, sodium hydroxide, ammonium chloride and ammonium sulphate are all positive, and

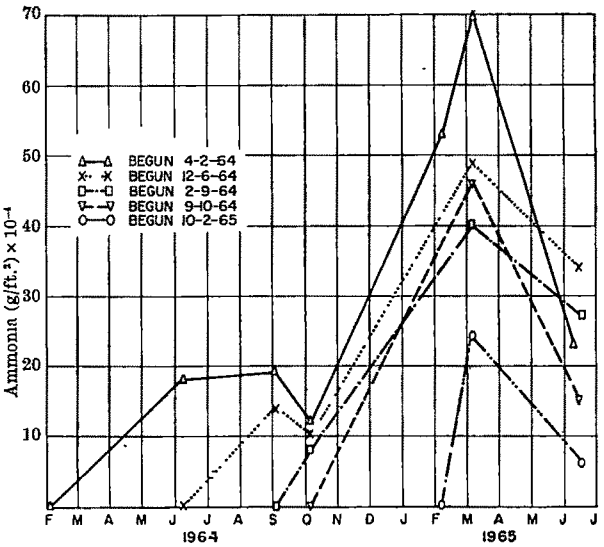

Fig. 1. Seasonal variation of the total ammonia retained on a specimen of mild steel

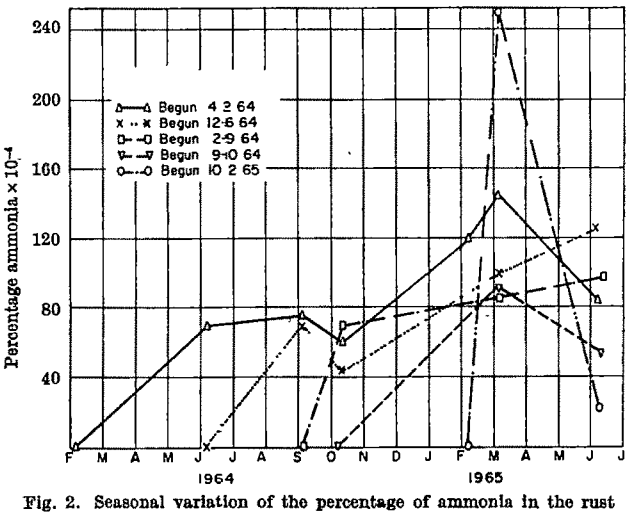

Fig. 2. Seasonal variation of the percentage of ammonia in the rust

* Present address: Corrosion Group, C.S.I.R., Pretoria, South Africa.

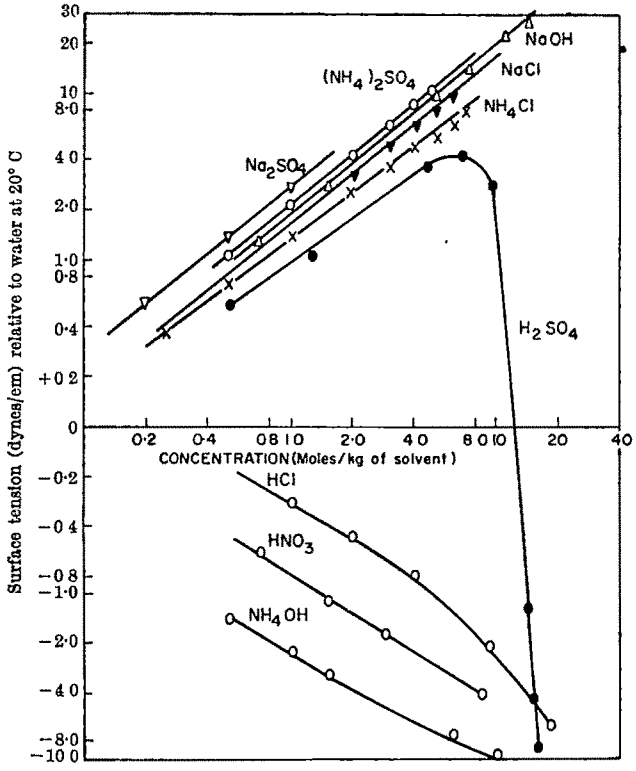

Fig. 3. Surface tensions of salt solutions at various concentrations

increase with concentration. Although not plotted in Fig. 3, the surface tensions for solutions of comparable salts of potassium, lithium, magnesium, and calcium are also greater than that of water, so that the phenomenon is apparently peculiar to ammonium compounds. Also included in Fig. 3 are the surface tensions of solutions of hydrochloric, nitric, and sulphuric acid. Solutions of the former acids also exhibit surface tensions lower than that of water, while sulphuric acid is distinctive in that the surface tension rises at first, then falls below that of water. Droplets of moisture on a steel surface are known to develop on outer annular cathodic zone where, in the presence of ammonium ions, the surface tension would fall, enabling the drop to spread. The presence of almost any other cation in solution would appear to cause such a drop to shrink. Thus the principal effect of ammonium in atmospheric corrosion may be that it promotes wetting and the subsequent involvement of greater areas of metal.

The severity of the attack experienced in the presence of ammonium salts may to some extent be due to the acidic nature of solutions of these salts, while the solubility of ammonia is an added factor. Brasher[7] has pointed out the error in designating certain electrolytes as corrosive and others as inhibitive, and stipulates that all electrolytes are corrosive in solutions of sufficiently great dilution. This would probably account for most of the discrepancies noted in the literature regarding the corrosiveness of the ammonium ion, and also indicated the importance of the ammonium ion in the initial stages of the corrosion process. It is in these stages that the hydroxide causes the corrosion to spread. At higher concentrations, such that ferrous ions are precipitated, the reaction will become blocked.

Considerations of the surface tension of the catholyte resulting from electrochemical corrosion in the presence of the ammonium salts, and observations on the high ammonia content of the adherent rust in the initial stages of corrosion are considered to suggest that the ammonium ion may play an important part in the mechanism of atmospheric corrosion.

OXIDATION OF TITANOMAGNETITES AND SELF-REVERSAL

By W. O'REILLY and S. K. BANERJEE
School of Physics, University of Newcastle upon Tyne

THE recent statistical correlation of petrology and the polarity of natural remanent magnetization of rocks[1] has led to a renewed interest in the possibility of self-reversal. It has been found that if rocks are categorized according to the degree of oxidation of the iron titanium oxide minerals[2], then the fraction of reversed rocks in each category increases with increasing degree of oxidation. The lowest category contains no reversed rocks and the highest category 80–90 per cent reversed rocks. Although this cannot be taken as definite proof of self-reversal, no attempt has yet been made to provide physical models by which oxidized titanomagnetites can be made self-reversing. The purpose of this article is to consider the oxidation processes and products and the consequent magnetic effects of the oxidation of titanomagnetites.

Oxidation of Titanomagnetites

(*A*) *To a mineral of spinel structure.* Cation deficient iron–titanium oxide spinels (analogous to maghemite, γ-Fe_2O_3) are found in Nature and are considered to be oxidation products of titanomagnetites. The cation distribution in single-phase spinel oxidized titanomagnetites has not been determined, but it is possible to apply the principles which govern cation distributions in titanomagnetites and other spinel oxides and make conjectures about how the cation distribution will change with oxidation.

The preference of Fe^{2+} ion for the tetrahedral sites of the spinel structure was first found by Verwey and Heilmann[3], who showed that if the chemical bonds in the spinel lattice are assumed to be purely ionic, the electrostatic energy dictates that tetrahedral sites should be occupied by the large divalent ions (for example, Fe^{2+}). However, chemical bonding in tetrahedral sites is not ionic but covalent[4] and the electrostatic energy lost by placing Fe^{3+} in tetrahedral sites is compensated by the energy of the covalent bond. This is the case in titanomagnetites[5] where tetrahedral sites are shared by Fe^{2+} and Fe^{3+} throughout most of the series. The absence of tetrahedrally sited Ti^{4+} is indicated by the neutron diffraction data of Ishikawa *et al.*[6].

The cation distribution in single-phase spinel oxidation products of titanomagnetites can be discussed on the basis of the foregoing data if the oxidation mechanism of Colombo *et al.*[7] for magnetite is extended to the titano-

magnetites. Cations diffusing through the crystalline lattice combine with adsorbed oxygen atoms at the surface which are ionized by the extra electrons of the Fe^{2+} ions. The speed with which the reaction occurs depends on the rate of diffusion of cations, and because of covalent bonding, tetrahedrally sited ions in spinels have a very low diffusion rate[8]. For this reason oxidation will occur largely at the expense of octahedral Fe^{2+} and the cation population of tetrahedral sites will remain constant. The cation distribution in the oxidation product will then be governed by the initial cation distribution, and the vacancies will occur largely in octahedral sites.

The degree of oxidation of the titanomagnetite

$$Fe^{2+}_{1+x}\ Fe^{3+}_{2-2x}\ Ti^{4+}_{x}\ O^{2-}_{4}$$

can be defined by an oxidation parameter z given by the reaction:

$$Fe^{2+} + \frac{z}{2}O \rightarrow z\,Fe^{3+} + (1-z)\,Fe^{2+} + \frac{z}{2}O^{2-}$$

and the number of vacancies produced per "molecule" is:

$$\frac{3 + \frac{z}{2}(1+x)}{4 + \frac{z}{2}(1+x)}$$

The number of Fe^{2+} ions per "molecule" is

$$\frac{(1+x)(1-z)\,4}{4 + \frac{z}{2}(1+x)}$$

The cation distribution may then be written:

$$Fe^{3+}_{1-\delta}\ Fe^{2+}_{\delta}\left[Fe^{2+}_{\frac{(1+x)(1-z)4-\delta}{4+\frac{z}{2}(1+x)}}\ Fe^{3+}_{\frac{2-2x+z(1+x)4}{4+\frac{z}{2}(1+x)}+\delta-1}\ Ti^{4+}_{\frac{4x}{4+\frac{z}{2}(1+x)}}\ \square_{\frac{\frac{3}{2}z(1+x)}{4+\frac{z}{2}(1+x)}}\right]O_4$$

where δ is the number of Fe^{2+} on tetrahedral sites and $\square$ denotes vacancies. From the arguments already given, δ will remain constant as oxidation proceeds and be equal to the value for the unoxidized titanomagnetite, δ_0. The range of oxidation parameter over which this is possible is shown on the $FeO - Fe_2O_3 - TiO_2$ ternary diagram (Fig. 1) and also for a number of values of x in Table 1. When all the octahedral Fe^{2+} ions have been oxidized the reaction can only proceed by the oxidation of tetrahedral Fe^{2+}, and for this range of composition δ is simply given by the total number of Fe^{2+} ions,

$$\frac{(1+x)(1-z)\,4}{4 + \frac{z}{2}(1+x)}$$

The oxidation of octahedral Fe^{2+} probably corresponds to the so-called first stage of oxidation of magnetite[7] which occurs quickly at a low temperature (1–2 h at 250° C). Further oxidation retaining the spinel structure may be impossible as the higher temperatures required to increase tetrahedral Fe^{2+} mobility could result in the decomposition of the cation-deficient spinel.

(*B*) *To a spinel-rhombohedral intergrowth.* The very common occurrence of intergrowths of ilmenite and magnetite led many workers in mineralogy to believe in the existence of a solid solution between the two, but Buddington and Lindsley[9] have shown that they are the result of oxidation of titanomagnetites either directly or by the formation of an intermediate cation-deficient spinel. The ilmenite (or ilmenite rich haematite-ilmenite solid solution, haemo-ilmenite) exsolves in the (111) planes of the spinel host.

Effect of Oxidation on Magnetic Moment

(*A*) *Spinel oxidation product.* Verhoogen[10] suggested an order–disorder mechanism for self-reversal which could apply to the case of spinel oxidation products. The disordered phase had a random distribution of the three types of ions and vacancies and the ordered one had a maximum amount of Fe^{3+} ions in tetrahedral sites, vacancies and Ti^{4+} ions in octahedral sites, with Fe^{2+} ions filling the remaining lattice sites. However, a random distribution of Ti^{4+} is not found in quenched samples of titanomagnetites. Thus it may not be probable in quenched oxidized titanomagnetites.

Another possibility is the oxidation of a ferrite with a *B* sub-lattice predominant moment (for example, a titanomagnetite) to a composition with an *A* sub-lattice moment. Using the cation distribution of the previous section, the variation of saturation magnetization, n_B, at 0° K varies with oxidation parameter, z, in the following manner:

$$n_B = \frac{56 - 24x - 4z + 4xz}{4 + \frac{z}{2}(1+x)} + 2\delta - 10\ \mu_B/\text{molecule}$$

For the first stage of oxidation, that is, $\delta = \delta_0$, it can be seen that for all compositions the spontaneous magnetization does not reverse. Further oxidation results in the reversal of magnetization for initial compositions corresponding to $x > 0{\cdot}6$ at the degree of oxidation given in Table 1 and shown in Fig. 1.

Table 1

Initial composition, x	Degree of oxidation, z First stage	Reversal
0	1	—
0·1	1	—
0·2	1	—
0·3	0 911	—
0 4	0·837	—
0·5	0·772	—
0 6	0 713	1·0
0·7	0 664	0·837
0 8	0·620	0·691
0·9	0 526	0 561
1·0	0·444	0·444

(*B*) *Spinel-rhombohedral intergrowth.* The intergrowth of ferrimagnetic and antiferromagnetic materials provides a system in which exchange anisotropy can operate[11]. The antiferromagnetic haemo-ilmenite exsolves in the (111) planes of the spinel host. It was first pointed out by Gorter[12] that as the (111) plane of the spinel has an oxygen arrangement which, like the (111) plane in haematite is

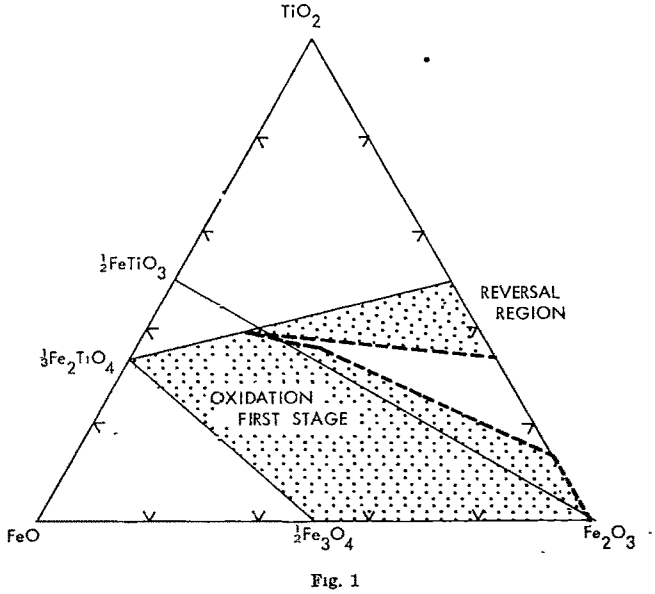

Fig. 1

close packed, and that as the unit cell dimensions are not too different it is possible for a super-exchange interaction to be active across the shared boundary layer. If, in such a system, the antiferromagnet is ordered in an external field above the Néel point of the ferrimagnet, and on cooling, the B sub-lattice spins of the ferrimagnet are coupled antiparallel to the cooling field, then the thermoremanent magnetization will be opposed to the external field.

Another mechanism for self-reversal lies in the decomposition of a highly oxidized cation-deficient spinel which has an A sub-lattice predominant moment. The remanence of the resulting magnetite–ilmenite intergrowth will be due to the B sub-lattice and so the decomposition will have the result of reversing the spontaneous magnetization of the system.

Discussion

Exchange anisotropy has been found in naturally occurring samples of maghemite partially inverted to haematite[13], but has not yet been reported for rocks containing oxidized titanomagnetites. A preliminary investigation of oxidized synthetic titanomagnetites[14] has not revealed exchange anisotropy.

Self-reversal by the oxidation of a titanomagnetite with a B sub-lattice predominant moment to one with an A sub-lattice predominant moment may not be possible because of the high degree of oxidation necessary for reversal. A further point is that the progressive increase in the number of vacancies may produce anomalous thermomagnetic curves of the L and N types It is more than possible that the Néel points will be below room temperature, or in the case of N-type curves, compensation points will be below room temperature and a B sub-lattice spontaneous magnetization will predominate at room temperature.

Because the cation distribution in quenched samples of titanomagnetites is now known[5], it seems probable that quenched samples of oxidized titanomagnetites will not have a random distribution of cations and that reversal by the order–disorder mechanism[10] is unlikely.

The production of a highly oxidized cation-deficient spinel at high temperatures is possible under the stabilizing effect of suitable magmatic gases. If this has the same cation distribution as the hypothetical oxidized titanomagnetite with the same composition, then an A sub-lattice moment will result. Subsequent decomposition to a magnetite–ilmenite intergrowth will then produce a reversal of magnetic moment. This would provide a physical model for explaining the correlation between reversed lavas[1,2] and the signs of a high degree of oxidation. To check this for natural samples, the bulk chemical compositions of titanomagnetites, with or without intergrowths, in rocks must be determined, and correlation between reversed polarity and chemical composition sought. If our hypothesis is correct, the bulk composition of reversed lavas should correspond to highly oxidized titanomagnetites of large x value. The most suitable technique for such an experiment would probably be electron probe X-ray microanalysis and chemical analysis.

DISTRIBUTION OF THE NUMBER OF CELLS IN A CLONE—A MONTE CARLO CALCULATION

By DR. C. W. GILBERT and A. H. W. NIAS

Paterson Laboratories, Christie Hospital and Holt Radium Institute, Manchester 20

WHEN mammalian cells from a monolayer culture are plated by the Puck technique[1] and each cell allowed to grow into a clone, then it is immediately obvious that there is a considerable range of the sizes of the clones. A detailed investigation of the distribution of the clone sizes for HeLa cells has been made by Nias, Gilbert, Lajtha and Lange[2] and a typical distribution shown in Fig. 1 has a mean clone size of twenty-four cells at 7 days; 10 per cent of the clones have less than four cells, 10 per cent more than forty-five cells and some clones have up to eighty cells. In such experiments cells are plated from an asynchronous exponentially growing population, and since the cells are at different phases of their cell cycle a range of clone sizes must be expected. However, if all cells had a constant generation time (time between consecutive cell divisions) then a total range of clone sizes of only twofold would be expected. The mean number of cells in the clones is observed to increase exponentially from the time of plating and so there is no net division delay which might disturb the early development of the clones.

The factors which might cause the wide distribution of clone sizes are: (*a*) a variation of the cell generation times; (*b*) the production of a proportion of cells at each division which undergo no further division; (*c*) a correlation between the generation times of the mother and daughter and between sister cells. A theoretical study has therefore been made of the influence of these factors

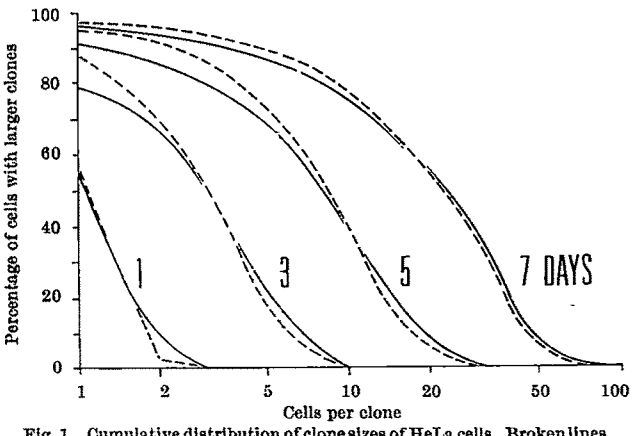

Fig. 1. Cumulative distribution of clone sizes of HeLa cells. Broken lines, experimental distribution. Fulllines calculated from the generation time distribution (*a*) of Fig. 2

on the clone-size distribution. As it was not possible to calculate an explicit probability distribution function for the clone sizes, an experimental numerical method was used, the so-called Monte Carlo method (for a general account of the methods see Hammersley and Handscomb[3]). Paper calculations are made for a sample number of clones (say, 100) and each clone is built up in detail by assigning to each cell a generation time determined in a suitable random way.

For the theoretical calculations it is necessary to have a clear set of basic assumptions. It is assumed that all cells are potentially the same (except for any cells which may have been designated sterile) and that essentially the same population could be grown from any individual cell. Cells are assumed to have generation times which vary in a random way but which conform to some postulated probability distribution function. The generation times may be quite independent of those of the ancestors of the cell or alternatively some degree of correlation between generation times of mother and daughter and between sister cells may be postulated. It is assumed that the cells which are plated are selected at random from a population which is in exponential growth and which has been growing long enough to be asynchronous.

The calculations were programmed for the *Atlas* computer at the University of Manchester and contain two essential parts: (*a*) the growth of a clone over an arbitrary time interval and (*b*) the selection of a cell to begin a clone. The basic steps in growing the clone from a time T_1 to a time T_2 are as follows: the clone at T_1 has n cells and the times, after T_1, at which they will next divide are stored in the first n locations of a store array. Each cell is scanned in turn until a cell is found the time for division of which is earlier than T_2. Division of this cell to create two new cells is then simulated. The next two random generation times are added to the time of this division to give the times at which the divisions of the two daughter cells will occur. The cell number is increased by one, and one daughter cell is stored at the end of the array of cells and the other in the place of the old cell. This cell is now re-scanned and, according to the time of its division, either another division made or the scan passed on to the next cell in the array. When the scan has passed all cells in the array (including the recently created ones), all cells will have their next time of division after T_2 and the total number of cells in the array is the size of the clone at T_2. In this way, starting from one cell at time zero, the size of the clone at a sequence of times $T_1, T_2, \ldots$ can be calculated.

The selection of the cells at zero time to start the clones must be made with care, because the times to their next division must conform to the statistics appropriate to an asynchronous exponentially growing population. The clones being grown by these calculations form just such a population and so previous clones provide material from which to sample for the next clone. The first cell of the first clone has, however, to be chosen in an arbitrary fashion, and, in effect, the whole population is grown from this first cell. A sampling population for initiating the clones is built up by storing the final cells of each clone and when the store is full by overwriting the earlier ones, so that an ever-changing population of finite size is maintained which has the proper statistical properties.

The random generation times required at each cell division are obtained as follows: first a random number, uniformly distributed in the interval 0–1, is generated by a standard computer routine, and then a transformation applied to it so that, in effect, a random selection from the postulated distribution of generation times is obtained. To produce correlations between mother–daughter and sister–sister generation times, two independent random times T_1 and T_2 are first obtained from a postulated distribution and then two generation times T_3 and T_4 are calculated from:

$$T_3 = \alpha T' + \beta T_1 + \gamma T_2$$
$$T_4 = \alpha T' + \gamma T_1 + \beta T_2$$

where T' was the generation time of the mother cell and:

$$\alpha + \beta + \gamma = 1$$

The degrees of correlations can be adjusted by the choice of α and β. A proportion of sterile cells can be obtained by assigning a very long generation time to some cells as a result of a draw of a random number. The distribution function and the correlations of the generation times actually used in the calculation are computed.

Before presenting the results of the calculations of clone-size distributions mention should be made of an interesting facet of the distribution of generation times in an exponentially growing population which was noticed during these calculations. If a random sample of cell divisions is taken from the growing population, then there is associated with each division one mother cell and two daughter cells. The average generation time of the mother cells is always less than the average of the daughter cells, except when all the generation times are equal and then the averages are also equal. The reason for the difference is because the selection of cell divisions gives an unbiased sample of daughter cells but a biased sample of mother cells; the mother cells with short generation times come from divisions later in the population growth and so will be overweighted. The relation between the mean generation time of the mother cells, T_m, and daughter cells, T_s, is given by the following equations:

$$T_s = \int_0^\infty f(t)t\,dt$$
$$T_m = 2\int_0^\infty f(t)e^{-bt}t\,dt$$
$$1 = 2\int_0^\infty f(t)e^{-bt}\,dt$$

where $f(t)$ is the differential distribution of the generation times of the daughter cells and b is the exponential growth-rate of the population. It should therefore be noted that when a distribution of generation times is observed by time-lapse cinematography it will be the distribution $2f(t)e^{-bt}$ which is most economically measured since the mother cell of all cell divisions except the first can be used.

On the basis of the foregoing methods, Monte Carlo calculations of clone-size distributions were first made on the assumption that there is no inter-cell correlation of the generation times and good agreement with experimental values could be obtained using a suitable distribution of generation times. This is shown in Fig. 2 (*a*) and

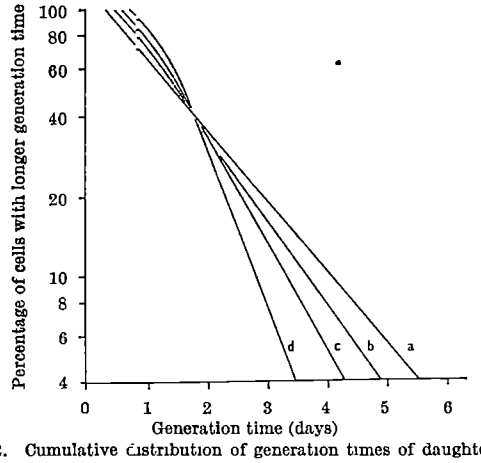

Fig. 2. Cumulative distribution of generation times of daughter cells

	Mean cell generation time, days	Coefficient of variation (per cent)	Correlation Mother–daughter	Correlation Sister–sister
a	1·96	82	None	None
b	1·90	73	0·07	0·12
c	1·86	61	0·14	0·30
d	1·77	45	0·31	0·53

the corresponding clone-size distributions in Fig. 1. No cell is assumed to divide before 0·35 day and thereafter the distribution of generation times has an exponential form, giving a total mean time of 1·96 days. Some other types of distributions were investigated, in particular sigmoid distributions based on the Gaussian curve, but these do not give the broad clone-size distribution observed. A similar type of calculation has been made by Hoffman, Metropolis and Gardiner[4].

Next the effect on the clone-size distribution of the production of a random proportion of sterile cells at each cell division was investigated. The clone-size distribution is only broadened significantly if the proportion of sterile cells is large; the Monte Carlo calculations of Till, McCulloch and Siminovitch[5] confirm this though they were made in a somewhat different context. Experiments show the HeLa cells to have a high plating efficiency and so the production of sterile cells is not an important factor in their clone-size distribution.

Calculations were made using various degrees of correlation between mother–daughter and sister–sister generation times and these gave a marked broadening of the clone-size distribution. The distribution of generation times shown in curves (*b*), (*c*) and (*d*) of Fig. 2 all predict clone-size distributions almost identical with those shown in Fig. 1, which had been calculated from (*a*) of Fig. 2. Correlation coefficients of the magnitude used here are not improbable since time-lapse ciné experiments of Dawson, Madoc-Jones and Field[6] have shown mother–daughter and sister–sister correlation coefficients of 0·19 and 0·56 for rat sarcoma cells in culture. All the distributions of generation times with the inter-cell correlations shown in Fig. 2 were obtained from the uncorrelated distribution of curve (*a*) by the method already described.

From the measurements of clone-size distributions alone it is not possible uniquely to determine the statistics of the cell generation times. Additional experimental evidence is needed and this can be got either from time-lapse cinematography of sample clones or perhaps from labelling experiments. Engelberg[7], and Anderson and Peterson[8] have shown that some information about the width of the generation time distribution can be obtained from measurements of the decay of an induced partial synchrony in a cell culture.

The results of these calculations show that the experimentally observed distribution of clone sizes can be adequately accounted for by a distribution of cell generation times with some degree of correlation between the generation times of the mother and daughter and the sister cells. It is emphasized that the wide distribution is largely developed during the early growth of the clone, for when the clone has more than about ten cells the variations average out and departures from the mean growth then become rare. The basic assumption of this model of clone development is that all cells are potentially alike. Cells will have generation times different from the mean because of stochastical variation of processes governing the development of the cell or because of local variations in its environment. It is not unlikely that some of these effects also influence the next generation of cells, but as the potentiality of all the cells is the same the effects do not persist through an indefinite number of generations.

IDENTIFICATION OF TWO FOWL β MACROGLOBULINS WITH PRECIPITATING ANTIBODY ACTIVITY

By JOCELYN CAREY and DR. R. FOWLER
Royal Children's Hospital Research Foundation
AND
M. NG
Commonwealth Serum Laboratories, Melbourne, Australia

ALTHOUGH there are well-documented similarities between avian and mammalian serum proteins, some significant differences have already been recorded. These include the faster electrophoretic mobility of chicken γ globulin[1,2], the high salt requirement for optimal precipitation of fowl antigen–antibody complexes, and the greater sensitivity[3] to 2-mercapto-ethanol of fowl 7*S** γ globulin[4].

A further difference between mammalian and avian species is evident from the results of two related investigations which are reported here. The first concerns the isolation and characterization of three fowl macroglobulins and, in the second study, two serum proteins associated with the early precipitating antibody response in fowls are identified.

Recently, attention has been focused on the antibody activity of fowl macroglobulins, but conflicting results have been obtained. Franklin[5], in an investigation of the physico-chemical properties of chicken macroglobulins by ultracentrifugation in sodium chloride, isolated two high-molecular-weight components from the serum. Benedict *et al.*[6], using chromatography of immune fowl serum on DEAE-cellulose, obtained three distinct macroglobulin fractions, each of which possessed antibody activity. In contrast, antibody could not be detected in a macroglobulin fraction obtained by elution of immune fowl serum from a 'Sephadex *G*-200' column[7]. Likewise, Orlans *et al.*[8] were unable to obtain positive evidence of macroglobulin in specific precipitates of fowl antiserum and bovine serum albumin.

Fractionation procedures investigated in the present work included column chromatography on DEAE-cellulose and on 'Sephadex *G*-200', and preparative ultracentrifugation. Immunoelectrophoretic analysis and analytical ultracentrifugation were used to determine the individual components of particular fractions. By stepwise elution with increasing concentrations of sodium chloride on DEAE-cellulose, only very low yields of macroglobulins were obtained. Column chromatography on 'Sephadex *G*-200' produced one peak of macroglobulin, but this was shown by immunoelectrophoresis to contain both α and β globulins. These methods were therefore discarded in favour of ultracentrifugation and, of several

* In this article the old-style electrophoretic nomenclature is used, and not the proposed World Health Organization nomenclature, as the structure of avian antibodies is not yet known.

modifications tested, sucrose gradient centrifugation was found to give the most satisfactory separation of high-molecular-weight components.

Fresh chicken sera were initially concentrated by spinning in a No. 40 rotor at 60,000*g* in a 'Spinco' model *L* preparative ultracentrifuge for 16 h at 4° C. The resultant supernatant was discarded and the pellet was taken up in a minimum quantity of *tris* buffer containing either 1·0 M urea or 0·5 M glycine at *p*H 7·6. Of the total protein in this preparation, 30–40 per cent was macroglobulin. A volume of 0·5 ml. of the dissolved pellet was layered on top of 20 ml. of 10–30 per cent sucrose gradient prepared in the same *tris* buffer.

After centrifuging in an '*S.W.*' swinging bucket rotor at 50,000*g* for 16 h, fractions of 0·5 ml. were collected by downward displacement. Alternate fractions were diluted with 3·0 ml. of the same *tris* buffer solution. Their optical densities, measured at 275 mμ in a Beckman spectrophotometer, were plotted against the fraction number. The remaining fractions were analysed by immunoelectrophoresis.

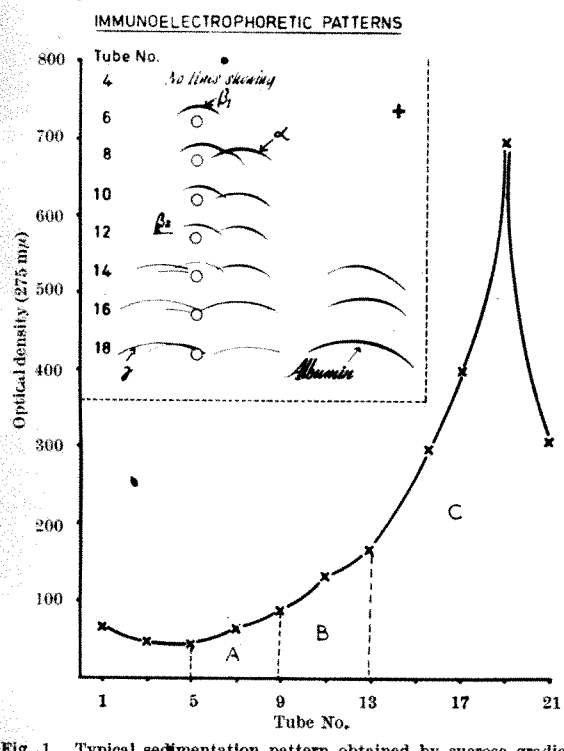

Fig. 1. Typical sedimentation pattern obtained by sucrose gradient ultracentrifugation of fowl serum, with inset showing immunoelectrophoretic patterns of alternate fractions developed against rabbit anti-fowl serum. Region *A* (fractions 5–9) contains 19*S* components, region *B* (fractions 10–13) contains 19*S* and >19*S* material, and region *C* (fractions 14–21) contains both 7*S* and 4*S* components

Fig. 1 shows a typical sedimentation pattern of the dissolved pellet after sucrose gradient centrifugation, together with immunoelectrophoretic patterns of alternate fractions.

In order to locate the macroglobulin components, analytical ultracentrifugation was carried out on several samples of the eluate using a 'Model *E*' analytical ultracentrifuge at 59,780 r.p.m. and 20° C. Region *A* (fractions 5–9) was shown to contain components with sedimentation constants of greater than 19*S*, while region *B* (fractions 10–13) contained 19*S* material and some material greater than 19*S*. Region *C* (fractions 14–21) contained both 7*S* and 4*S* components. As no trace of 7*S* material was evident in Region *B*, the line which first appears in the β_2 region in fraction 12 represents a β_2 macroglobulin and cannot be attributed to the 7*S* γ globulin component. This latter protein appeared in subsequent tubes and gave a characteristic immunoelectrophoretic line clearly distinguishable from that of the 19*S* macroglobulins (Fig. 1, fractions 14–18).

The macroglobulins, therefore, were eluted in fractions 4–13, and by immunoelectrophoresis were shown to contain three components: two β globulins and one α globulin.

Of the two β macroglobulin components, the β_2 macroglobulin has been recorded previously[9], and has immunoelectrophoretic characteristics similar to human β_2 macroglobulin. The other is a macroglobulin which does not migrate from the origin and therefore we suggest that it be referred to provisionally as a β_1 macroglobulin. Antibody studies to be described below discount the possibility that this is denatured material at the origin. Dreesman *et al.*[10], in a recent investigation of a component in chicken serum of similar electrophoretic mobility, reported on its antibody activity and called it a β_2A globulin. However, its position relative to the transferrin and γ globulin lines is different from that of human β_2A globulin, which, moreover, has a lower sedimentation range.

Fowl serum, therefore, possesses two β macroglobulins compared with one in human serum.

Having established the immunoelectrophoretic characteristics of these 19*S* components, we then sought to identify the type of proteins involved in the antibody response of fowls to bovine serum albumin (BSA). Fowls were given immunizing doses of BSA in Freund's incomplete adjuvant. Each bird received two injections of antigen (40 mg/kg) given 16 days apart. Serum samples were collected daily. A previously described modification[11] of immunoelectrophoresis was used to localize in the immunoelectrophoretic spectrum those globulins which possessed antibody activity. The immune serum was subjected to electrophoresis and a solution of the immunizing antigen was placed in the outer troughs. However, since the optimal precipitation of fowl antigen–antibody complexes occurs in the presence of high salt concentrations, a further modification was introduced. Following electrophoresis of the immune serum, the agar strips were removed from the glass supports and placed on agar slabs prepared in 10 per cent saline.

No antibody was detected in the sera for 5 days after the first injection or for 3 days after the second injection. On the sixth day after the second injection, two lines of specific antigen–antibody precipitate were evident (Fig. 2*a*), one remaining at the origin and one extending from the origin into the β_2 region. Thereafter the β_2 line diminished and the β_1 line became more prominent

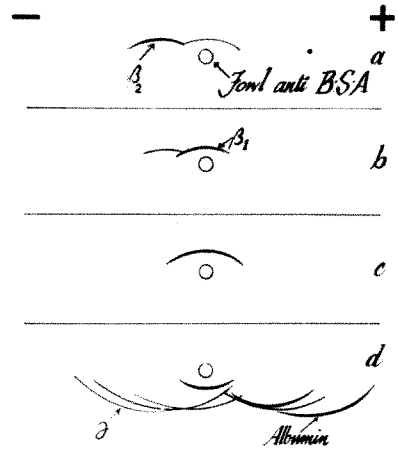

Fig. 2. Localization of antibody activity in immunoelectrophoretic spectrum of fowl antibody to BSA. Diagrams 2*a*–2*c* represent lines of precipitation of electrophoresed fowl anti-BSA developed by linear diffusion against BSA, and represent progression from a preponderance of β_2 to β_1 type antibody: (*a*) at 6 days; (*b*) at 10 days; (*c*) at 15 days. For reference, diagram 2 (*d*) is a normal immunoelectrophoretic pattern of fowl anti-BSA serum developed against rabbit anti-fowl serum

(Fig. 2*b* and *c*). There was a temporary disappearance of these lines for 3 days immediately following the second injection of antigen, after which only the β_1 line was observed.

The β_2 line of anti-BSA precipitating antibody was distinguished from 7*S* γ globulin by direct comparison with the conventional immunoelectrophoretic pattern of fowl anti-BSA serum developed against rabbit anti-fowl serum (Fig. 2*d*). No 7*S* γ globulin line was seen using the "inverse" immunoelectrophoretic technique at high salt concentration.

Our failure to observe any 7*S* γ globulin precipitating antibody in the primary response of fowls to BSA is at variance with the findings of Dreesman *et al.*[10]. They have already noted considerable variation in the relative preponderance of 19*S* or 7*S* anti-BSA antibodies made by individual fowls, and suggest that this may be due to variations in either the exact nature of the antigen or the particular technique used to test antibody response. It may well be that the "inverse" immunoelectrophoretic technique in high salt concentration used in this investigation is more sensitive in detecting macroglobulin than 7*S* γ antibodies, but it has nevertheless enabled us to distinguish two separate β globulin components within the class of anti-BSA precipitating antibodies.

The sequence of appearance of antibody types reported here provides evidence that the β_1 line is not due to denatured material such as is sometimes seen at the origin, or to non-specific heterophil antibody activity[10].

Thus early fowl antibody may be associated with both β_1 and β_2 globulins. Since these two globulins share the immunoelectrophoretic characteristics of the two β macroglobulins isolated by sucrose gradient centrifugation, the results of the two investigations considered together suggest an immunological role for the two fowl β macroglobulins. Although no precipitating antibody activity was observed in the α globulin region, a reaction of antigenic identity was demonstrated between the α and β_1 macroglobulin fractions (Fig. 3). These two fractions were pooled and subjected to immunoelectrophoresis against antiserum from rabbits injected with these two fractions. The reaction of identity between these two macroglobulins is evidence that they share at least some common protein sub-unit in their structure and synthetic mechanisms, even if they do not share the antibody combining configurations.

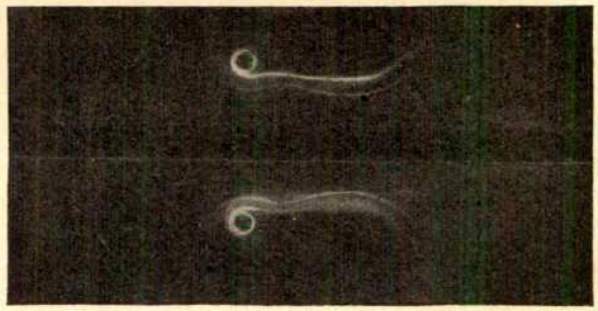

Fig. 3. Precipitation patterns obtained by electrophoresis of pooled α and β_1 fowl macroglobulins and linear diffusion against rabbit antiserum potent against these two fractions. This antiserum was obtained by booster injections of pooled α and β_1 macroglobulins into rabbits already producing polyvalent anti-fowl whole serum antibodies. This explains the faint precipitin lines seen here against trace contaminants of β_2 and γ globulin fractions

This finding prompts speculation concerning a possible link between mammalian immunoglobulin synthesis and the non-specific inflammatory response of α_2 globulin levels. A search for shared polypeptide chain structures between mammalian α_2 and γ globulins might well be profitable.

ELIMINATION OF NON-SPECIFIC ANTIBODIES FROM RABBIT ANTISERA USING ACETONE-PRECIPITATED SOLUBLE PROTEINS

By B. SCHMIDT, Y. HOSOKAWA and D. HARTMANN

Institut für Hygiene and Medizinische Mikrobiologie, Freie Universität, Berlin

AFTER repeated injections of influenza virus or its subunits into animals, non-specific antibodies were often found to be present in the antisera. These non-specific antibodies are directed against components of the host cells and may cause reactions, for example, in the complement fixation test and the fluorescent antibody technique.

If the same antigen is used for the induction of antibodies and the respective antigen–antibody reactions, it is necessary to eliminate the non-specific component from either the antigen or the antiserum or from both.

A number of methods are available for the elimination of non-specific immunoglobulins or free labelling agents: serum dilution, dialysis, serum adsorption with preparations of tissue or cells[1–4], tissue powders[5,6], tissue homogenates[7], charcoal[8], gel-filtration on 'Sephadex'[9], electrophoresis[1,10], chromatography on cellulose ion-exchangers[11–15], adsorption with antigen fixed to slides[16], and dissociation of specific antigen–antibody complexes[17,18].

For the complete removal of the non-specific antibodies we have used the homologous antigen in form of a water-insoluble protein precipitate of chorioallantoic fluid, prepared by a modified method of Coons *et al.*[6]. Using this powder for adsorption of the non-specific antibodies, no significant drop of virus specific complement fixation titre (CFT) and haemagglutination inhibition titre (HIT) of the antiserum could be observed. For preparation of protein powder see Fig. 1.

Influenza virus A_2/Singapore 1/57 was propagated in 10–12-day-old chicken embryos and purified by differential centrifugation. Subunits were prepared by treatment with ether-'Emasol-1130'[19], adsorption, and elution with fowl red-cells. Haemagglutinin was purified by chromatography on DEAE-cellulose[20], *s*-antigen by centrifugation[21]. Rabbits were immunized with either virus particles, haemagglutinin or *s*-antigen by one intramuscular and three intravenous injections. The immunosera were obtained two days after the last intravenous injection to produce virus or haemagglutinin antibodies. Ten days after the last intravenous injection, blood was withdrawn to obtain *s*-antibodies. The complement fixation technique was performed in accordance with the method of

Lief *et al.*[3]. For the haemagglutination inhibition technique on 'Plexiglass' plates we used serial two-fold dilutions of 0·25 ml. antiserum (RDE-incubated), 16 haemagglutinin units per 0·25 ml. and 0·5 ml. of 0·5 per cent fowl red cell suspension. The antisera from rabbits containing non-specific antibodies were shaken over-night at 4° C with protein powder followed by centrifugation at 2,000*g* for 15 min. Only 0·04 per cent of the protein powder was resolved after shaking for 24 h in isotonic sodium chloride solution at room temperature. The results of the serum treatment are shown in Table 1.

Table 1. ELIMINATION OF NON-SPECIFIC ANTIBODIES FROM RABBIT SERA

Experiment	Amount of powder (mg/ml. serum)	Antigens for CF-reaction infected CAF CFT	non-infected CAF CFT
	50	200 + + + +	< 5
	25	200 + + + +	< 5
1	10	200 + + + +	50 +
	5	200 + + + +	100 +
	0	400 +	100 + + +
	15	320 +	20 + + + +
	10	320 +	40 + + + +
2	5	320 +	40 + + + +
	0	320 +	80 + + + +
	0 without shaking	320 +	80 + + + +
	50	640 + + + +	< 5
	25	640 + + + +	< 5
3	10	640 + + + +	20 + +
	5	640 + + + +	20 + + +
	0	640 + + + +	20 + + + +

(Experiments 1 and 2: anti-*s*-sera; experiment 3: anti-haemagglutinin-serum.) Elimination by shaking the sera with protein powder over-night at 4° C. CFT, reciprocal serum dilution giving complete (+ + + +) or decreasing degrees (+ + +, + +, +) of fixation of complement.

The effect of adsorption corresponded to the amount of powder used. In the aforementioned experiments, 20 mg of protein powder caused complete adsorption of the non-specific antibodies. This indicates that elimination of non-specific antibody is due to an antigen–antibody reaction.

If a protein powder is prepared by only one short treatment of soluble protein, with acetone, the same amount of powder is required for the elimination of the non-specific antibody, but a higher resolution of powder takes place in this case.

In Fig. 2 the amount of protein powder is plotted against the level of resulting CFT of antibodies after treatment.

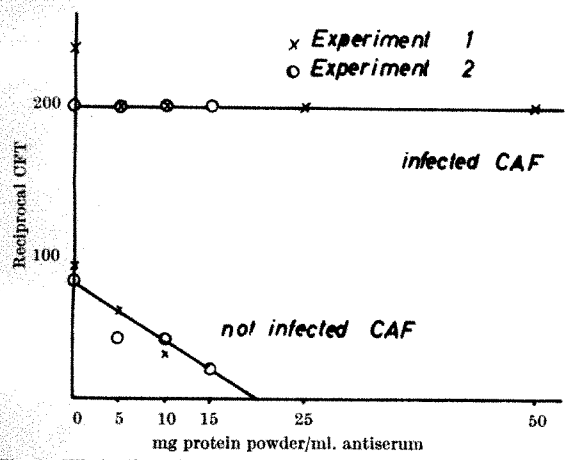

Fig. 2. Elimination of non-specific antibodies by protein powder from rabbit antisera immunized with *s*-antigen. Infected and non-infected chorioallantoic fluids in a constant dilution of 1 : 4 were used as antigens against serial dilutions of anti-*s*-serum for the CF-test. CFT see Table 1. CFT 1 : 320 + is plotted as CFT 1 : 200

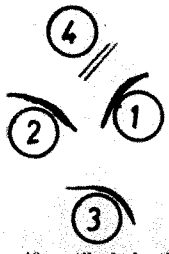

Fig. 3. Detection of non-specific antibody by the agar gel diffusion technique of Ouchterlony. (1) Anti-*s*-antigen serum before adsorption. (2) The same serum after adsorption. (3) Non-infected CAF. (4) RNA-containing fraction extracted from infected chorioallantoic membranes after removal of haemagglutinin by fowl and sheep red cells and after centrifugation of the *s*-antigen (40,000 r.p.m., 120 min, Spinco *L*, rotor 50)

It shows that the level of specific antibody remains constant in the serum, while the non-specific antibody is adsorbed.

Furthermore the adsorption of the non-specific antibody from anti-*s*-serum has been examined by agar gel diffusion. The corresponding data are shown in Fig. 3.

There was no precipitation of the adsorbed antiserum with the non-specific protein of allantoic fluid. By agar-gel diffusion no difference of the antigenicity was observed between *s*-antigen from the membrane and another from virus particles disintegrated with ether.

The effects of protein powder treatment on HIT and CFT are shown in Table 2. Adsorption was carried out with anti-virus, anti-haemagglutinin and anti-*s*-antigen sera. Non-specific antibodies could be adsorbed without visible decrease of virus-specific ones.

Table 2. EFFECTS OF PROTEIN POWDER TREATMENT ON HIT AND CFTP, USING ANTI-VIRUS-, ANTI-HAEMAGGLUTININ-, AND ANTI-*s*-ANTIGEN SERA

Antisera	Antigen CAF	Powder mg/ml. serum	Before treatment CFT	HIT	After treatment CFT	HIT
Anti-	infected	10	800 + +	2000	800 + +	2000
virus	not infected		50 +	0	< 5	0
Anti-	infected	10	880 + +	1200	800 + +	1200
hemaggl.	not infected		50 +	0	< 5	0
Anti-	infected	20	400 + + + +	0	400 + + + +	0
s-antigen	not infected		100 + + +	0	< 5	0

The use of powder from a soluble protein seems preferable for the following reasons: (1) The existence of corresponding antigens for adsorption of non-specific antibodies. (2) The absence of solid cell particles. (3) The low or non-existent adsorbing activity for specific antibodies. (4) The lack of dilution of the immune serum. (5) The insolubility of the powder in the sera. (6) The constancy of the antigenicity after storage for 1 week at 37° C. (7) The convenience of producing large amounts. (8) The possibility of sterile conditions.

The use of soluble proteins only, instead of cells, tissues, or tissue homogenates, may be more effective in the adsorption of non-specific antibodies.

ANTIBODY FORMATION AND EXPERIMENTALLY INDUCED CHIMERISM IN VERY YOUNG RABBITS

By CHI-TAO CHOU, S. DUBISKI and B. CINADER

Subdivision of Immunochemistry, Division of Biological Research, Ontario Cancer Institute; Departments of Medical Biophysics, Pathological Chemistry and Medicine, University of Toronto and the Toronto Western Hospital

THE injection of antigens into animals may result in one of three possible events: immunological tolerance may be induced, antibody may be formed, or there may be failure to react to the antigen in any detectable way. Which of these three reactions is observed depends on the nature and quantity of the administered antigen and on the age and immunological experience of the injected animal[1]. We shall show that, given identical quantities of human albumin, any of these three responses may be observed in rabbits, depending on the form in which the antigen was administered to the new-born animal.

If new-born rabbits were given 2·8 μg N of human albumin, within 36 h of birth, antibody could not be detected in the circulation in any of these animals during the subsequent 4 weeks. Tests for the elimination of radioactively labelled (iodine-131) human albumin[2] showed that 28 per cent (2/7) of 30-day old animals and 11 per cent (3/27) of 70-day old animals were tolerant (compare with ref. 3). If a similar quantity of protein (1–4 μg N) was associated with nucleated adult rabbit cells, and was then injected into new-born animals, a considerable proportion of the animals contained antibody to human albumin in their circulation 2–4 weeks later. The questions arose whether, (*a*) antibody formed in these circumstances was the product of donor cells or whether it was synthesized by the recipient animals; and if it is the latter, whether (*b*) a product of the donor cell can be detected. The experiments described here were designed to answer these questions. They showed that the antibody induced by antigen, associated with nucleated donor cells, was produced by the cells of the recipient animals, and that in some recipient animals, soluble products from donor cells were formed and could be detected in the circulation for long periods of time.

Cells of normal donors were obtained from thymus, lymph node or as peritoneal exudates, rich in mononuclear cells. The separated cells (from six unrelated donors) were incubated for 30 min at 37° C with radioactively labelled (iodine-131) human albumin and were then washed ten times with Eagle's basal medium. The amount of human albumin associated with the washed cells was determined by radioactive counting. Twelve hours and 36 h after birth, rabbits were injected with 1–4 μg N human albumin, associated with about 80×10^6 lymph-node cells, thymus cells or with peritoneal exudate cells, rich in mononuclear cells. The injected animals were then bled at weekly intervals.

Within 2–3 weeks after the neonatal injection with albumin-treated cells, the majority of the animals had circulating antibody to human albumin which could be demonstrated by its capacity to agglutinate tanned erythrocytes, sensitized with human albumin[4]. Antibody was induced by albumin-treated peritoneal exudate cells (rich in mononuclear cells) in 43/56, by albumin-treated lymph-node cells in 42/72 and by albumin-treated thymus cells in 18/33 of the injected animals.

We had thus found that a quantity of human albumin, which had induced tolerance in 28 per cent of injected animals, when given in soluble form, induced antibody in 55–80 per cent of injected animals, when given in association with nucleated cells. It seemed quite possible that this difference in responsiveness was due to the production of antibody by the transferred cells, as had been found by Harris *et al.*[5] (see also refs. 6–10) under different experimental conditions. To investigate this possibility, we used allotypic markers for the discrimination between cell products of donor and recipient animals.

Animals, used as recipients and donors, differed in the allotypic specificity of their immunoglobulins and possessed either allotypic specificity *A*4 or *A*5, which are known to be located on the light chains and to be determined by two allelic genes A_b^5 and A_b^5 (ref. 11).

Antibody produced by animals injected with cell associated human albumin was removed from the sera by incubation with human albumin, covalently linked to cellulose particles[12,13]. After incubation, the cellulose particles were separated from the serum by centrifugation, were washed, and antibody was eluted at *p*H 3·0. The eluate, adjusted to *p*H 7·4, was then tested for antibody activity and for the presence of allotypic specificities of donor and recipient types.

The quantity of allotypically defined immunoglobulins in isolated antibody or in whole serum was estimated by two techniques: by haemagglutination inhibition[14] and by single diffusion[15]. The first of these techniques is capable of detecting very small relative quantities of allotypically marked immunoglobulin, but with a low level of precision. The second method gives relative immunoglobulin quantities with an error of 5–10 per cent, but is much less sensitive than the first. Where both methods could be used, the agreement between relative values obtained by these two methods was good.

The quantity of antibody recovered from the 'immuno-adsorbent' was generally between 25 per cent and 100 per cent of the total antibody, but for serum from 2–3-week-old animals was usually lower: between 5 per cent and 20 per cent.

The isolated human albumin antibody from animals injected at birth always contained allotypic specificity of the recipients and never the allotype of the donor of the transferred cells.

It seems reasonable to assume that the recovery of antibody of donor and recipient origin would be comparable and that low recoveries of early antibody will therefore not affect the validity of our conclusions. We conclude, therefore, that transferred cells do not synthesize an important fraction of the antibody; and that the remarkable difference between the response of new-born animals to the same antigen in soluble form and in association with nucleated cells must be attributed to the potentiation of the immunogenicity of the antigen and presumably to some kind of mediation between antigen and the synthesis component of the immune apparatus of the new-born animal.

While we had thus shown that the transplanted cells did not produce antibody to human albumin, it remained to be seen whether or not they or their descendants produced any product, detectable in the circulation. To test for this, we examined and assayed the immunoglobulins in the whole serum of animals, which had received human albumin associated with nucleated cells, using the same techniques as were previously used for the examination of the specificity of isolated antibody to human albumin. Although all the antibody to human albumin was synthesized by the recipient, substantial quantities of immunoglobulin of donor type, not directed against human albumin, were found in the serum.

The allotypic specificity of the donor cells could be observed, in most recipient animals, for a period of 4–10 weeks with a continuous decline in concentration until it was no longer detectable (Fig. 1). The half-life

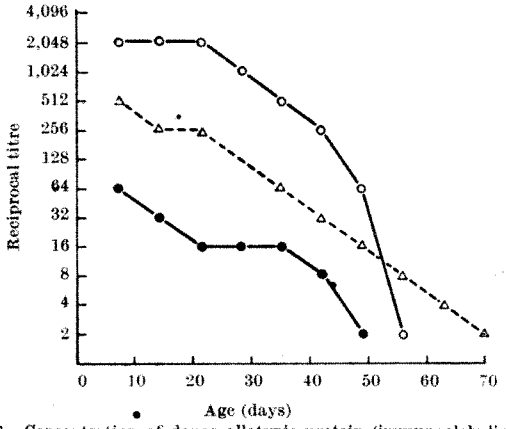

Fig. 1. Concentration of donor allotypic protein (immunoglobulin) in the serum of rabbits injected at birth with nucleated cells. Allotype of recipient animals was A5 and allotype of donor animals was A4. Concentration of allotypic immunoglobulin was measured by agglutination-inhibition. ———●——— and ———○———, Concentrations of allotypic protein of donor type in a rabbit injected at birth with lymph-node cells; – – – △ – – –, concentration of allotypic protein of donor type in a rabbit injected at birth with cells from peritoneal exudates, rich in mononuclear cells

of disappearance, measured by agglutination-inhibition, was about 7 days (not corrected for increasing body-weight) (Fig. 1). So as to be able to interpret the significance of half-life measurements, we determined the half-life of allotypically labelled immunoglobulins under conditions where synthesis could not affect its concentration, that is, after passive transfer of immunoglobulin of one allotype to new-born animals, homozygous for another allotype. The half-life determined under these conditions was 7 (± 1) days.

These results indicate that there was no synthesis of immunoglobulins by the transferred cells during the period of observation. However, in other individuals of the injected group, synthesis by the transferred cells did occur (Fig. 2). In 8 per cent (2/24) of the animals injected with albumin attached to lymph node cells and in 28 per cent (7/25) of the animals injected with thymus cells, the foreign allotypic specificity could be detected and measured for 5 months.

In the circulation of 8 per cent of animals injected with lymph-node cell suspensions we observed an immediate increase in the concentration of the foreign allotypic specificity, followed by a decline and then a second increase which lasted for about 2 months; later, the concentration of allotypic specificity remained fairly constant. In 28 per cent of the animals injected with thymus cell suspensions, there was a continued increase in concentration for the first 2 months of life. As in the case of animals injected with lymph node cells, the concentration of "foreign" allotypic specificity reached a fairly constant level when the animals were 8 weeks old. This stabilized concentration was maintained throughout the period of observation. In the case of the animals which had received thymus cells, the concentration was close to that of untreated heterozygous (A^4/A^5) animals, and was 10–20 per cent of this value in animals which had been injected with lymph node cells (Fig. 2).

Our experiments do not allow us to decide whether information transfer to recipient cells or colonization by donor cells is responsible for the formation of the allogeneic immunoglobulin. It seems reasonable, however, to assume that chimerism[16–31] has been produced within a non-inbred animal population by the transfer of cells to new-born animals and that some of these animals produced the allogeneic allotype for the whole period of observation, and at concentrations identical with those of heterozygous animals.

The question arose whether the allotypic specificity of the donor animal could be demonstrated only in the homologous organ of chimeric rabbits, or whether it could be found in other parts of the body as well. To test this, lymph node, spleen, and bone marrow cells from an animal, in which the specificity of the donor had persisted for 6 months, were transferred to a new-born animal, and we could show the appearance and rapid decline of the foreign allotype possessed by the donor, in recipients of lymph-node cells (10/13), thymus (3/11) and spleen (2/2) but not of bone marrow cells (0/6).

It should be emphasized that the weight increase of the chimeric animals, produced in our experiments, was quite similar to that of normal animals and that there was no indication of runting.

We have thus observed that cell transfer within an allogeneic population has resulted in a remarkably high incidence of long-lasting synthesis of a serum protein which carries the marker of the gene-product of transferred allogeneic cells.

The diphasic appearance of the foreign immunoglobulin in the rabbits, injected with lymph-node cells, in which a prolonged increase in the concentration of allogeneic protein was observed, is of considerable interest (Fig. 2). It seems quite possible that, during the first phase, immunoglobulin was being produced by cells which were already fairly far advanced in their differentiation at the time of transfer and that the decline of immunoglobulin concentration reflected the life span of these differentiated cells. The second, long-lasting rise might be attributable to the synthetic activity of cells, much less differentiated at the time of transfer. Products from these cells would constitute an appreciable fraction of the immunoglobulins only after cell differentiation and cell division had progressed sufficiently. The difference between allotype production in animals injected with lymph-node cells and with thymus cells can, in all probability, be attributed to higher concentration of relatively undifferentiated cells in the thymus cell population, so that the initial phase of production by mature donor cells would be obscured, even if it should occur.

In summary, we have shown that the injection into new-born rabbits of a small quantity of albumin, associated with nucleated cells, induces an antibody response in the majority of animals, whereas the same quantity of antigen in solution fails to stimulate antibody formation or induces tolerance. The antibody produced after the injection of albumin, associated with nucleated cells, is of recipient origin. However, immunoglobulin carrying the marker of donor cells can be demonstrated in the

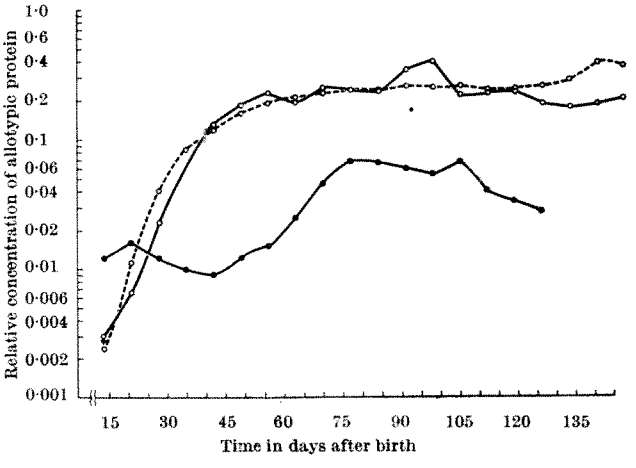

Fig. 2. Concentration of donor allotypic protein (immunoglobulin) in the serum of rabbits injected at birth with nucleated cells. Comparison between concentration of allotypic immunoglobulin in chimeric animals and in normal heterozygotes. Allotype of recipient animals was A5 and allotype of donor animals was A4. Allotype concentration was measured by a single diffusion method. ———○———, Concentration of allotypic protein of donor type in a rabbit injected at birth with thymus cells; ———●———, concentration of allotypic protein of donor type in a rabbit injected at birth with lymph-node cells; – – – ○ – – –, concentration of allotypic immunoglobulin in normal heterozygous animal

recipient animals, and may reach serum concentrations comparable with those normally present in animals which are heterozygous with respect to the marker.

We thank Mrs. S. Schultz for her technical assistance. One of us (C-T. C.) acknowledges support by the W. P. Caven Memorial Fund fellowship. The investigation was supported by the Canadian Arthritis and Rheumatism Society, by the Medical Research Council of Canada, the National Cancer Institute of Canada, and by the U.S. National Institutes of Health.

INTRANUCLEOLAR DEOXYRIBONUCLEIC ACID COMPONENTS IN INSECT CELLS AS REVEALED BY ELECTRON MICROSCOPY

By DR. J. JACOB
Institute of Animal Genetics, University of Edinburgh

IN most plant and animal cells the nucleolus is associated with a particular chromosome of the complement at a specific region called the nucleolar organizer. As seen in usual cytological preparations, the chromatin of the organizer or the "associated chromatin" may be perinucleolar in many cells, including mammalian cells, or it may be at the central portion of the nucleolus as in chironomids. The deoxyribonucleic acid (DNA) of the organizer is sometimes referred to as "nucleolar DNA", but this part of the nucleolar-chromosomal complex is a specialized locus of the chromosome. Apart from it, no DNA is demonstrable in nucleoli in general by light microscope cytochemical methods and thus the widely held view that this organelle is devoid of DNA. In agreement with this view, DNA appeared to be absent in the nucleolus of the salivary gland cells of the chironomid *Smittia*[1,20]. This article presents evidence from electron microscope investigations to show that chromatin-like material which appears to contain DNA occurs inside the nucleolus proper and this will be referred to as "intranucleolar DNA".

The salivary glands were fixed for 20 min in cold (4° C) 10 per cent formalin, 6·5 per cent glutaraldehyde or a mixture of acrolein–formalin, 10 per cent each, in phosphate buffer at *p*H 7·4–7·6. Dehydration as well as embedding were in glycol methacrylate as described by Leduc, Marinozzi and Bernhard[2,3]. Sections were cut on a Porter–Blum 'Servall' microtome and subjected to various treatments including enzymatic extractions. The enzymes used were: 0·1 and 0·2 per cent RNase (Lights, five times crystallized) in distilled water adjusted to *p*H 6·8; 0·1 per cent DNase (Lights, once crystallized) in distilled water, *p*H 6·2; 0·5 per cent pepsin (Lights, twice crystallized) in 0·1 N hydrochloric acid; 0·33 per cent trypsin (Difco, 1 : 250) in distilled water, *p*H 8, and 0·25 per cent pronase (Calbiochem, grade *B*) in phosphate buffer at *p*H 7·4. Sections were stained either in 2 per cent aqueous uranyl acetate for 1 h or this followed by lead citrate[4] for 40 min and a 20-min stay in water.

A high-power electron micrograph of a section not treated with any enzyme, but double stained with uranium and lead, is shown in Fig. 1. The interesting feature here is the presence of extremely dense fibrillar masses dispersed in the nucleolus. Both in fine structure and electron density, they bear a close resemblance to the contents of the chromosomes. The fibrillar masses were not present in all sections of the nucleolus; when present, their numbers varied from one to four except in the few sections of the central portions of the nucleolus where a good number of them occurred. The larger masses (up to about 450 mμ in average diameter in this section) were situated close to the site of the organizer and the smaller ones (65–160 mμ in diameter) were dispersed in the inner regions of the nucleolus.

Many experiments were carried out with enzymes either singly or one followed by another and on material fixed in different aldehydes. The results which have a bearing on the chemical organization of the nucleolus at the ultrastructural level will be reported later (together

with the methods in detail) and only those relevant for the present discussion are presented here.

If sections of glutaraldehyde-fixed glands are treated first with pepsin for 1 h and then with RNase also for an hour (all at 37° C), the nucleolar constituents are markedly extracted compared with normal. In such preparations the chromosomes are retained (Fig. 2) and small dense patches of chromatin-like material are seen distributed all over the nucleolus. In Fig. 2, the large patch close to the nucleolar organizer measures about 600 mμ in average diameter and is probably continuous with the chromatin of the organizer. The smaller ones within the nucleolus vary in size with average diameters of 50–170 mμ. If the order of enzymatic extractions is reversed and RNase is used first, most of the nucleolus is still removed, but the appearance of the chromosome is different. In these preparations, too, material as in chromosomes has been

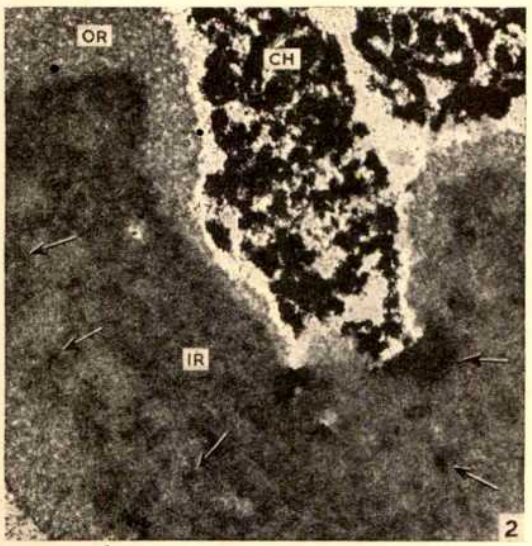

Fig. 2. Nucleolus and chromosomes (*CH*) after extraction, first with pepsin, and then with RNase. Note the small patches of chromatin-like material (arrows) dispersed in the nucleolus. The inner region of the nucleolus (*IR*) is denser than the outer (*OR*) in such preparations and the chromatin patches occur predominantly in the former region. One or two large patches are probably continuous with the chromatin of the organizer. (Glutaraldehyde fixed and double stained. × 9,300)

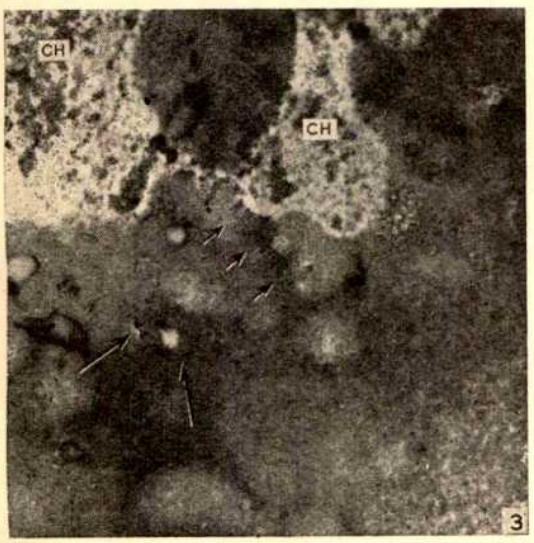

Fig. 3. Nucleolus and chromosome after extraction with RNase followed by pepsin. Material of similar appearance as chromatin (*CH*) is observable inside the nucleolus (arrows). Some of these appear to be continuous (small arrows) with organizer chromatin and others (large arrows) isolated. (Glutaraldehyde fixed and stained in uranyl acetate. × 10,000)

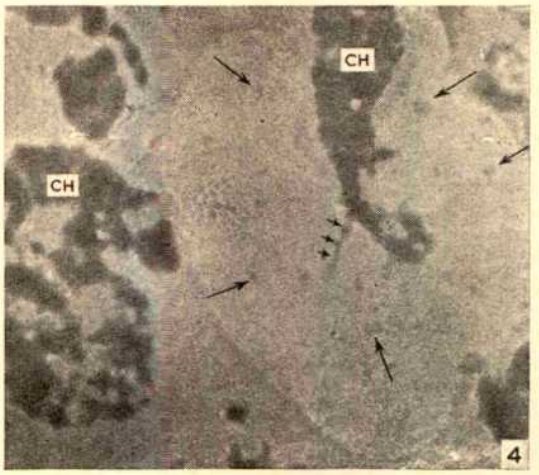

Fig. 4. Nucleolus and chromosomes (*CH*) as they appear after extraction with pronase and RNase. Note small patches of dense chromatin-like material (arrows) dispersed inside the nucleolus which appears almost as negative image of control. An extension of the organizer chromatin is indicated (small arrows). (Acrolein-formalin fixed and stained in uranyl acetate. × 6,600)

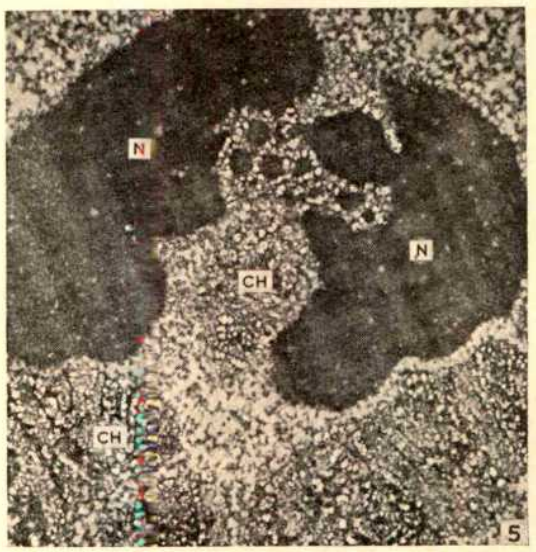

Fig. 5. A section extracted with DNase. See the chromosomes (*CH*) riddled with holes or empty spaces. Similar holes are also present in nucleolus (*N*) which otherwise appears unaffected by DNase. No holes noticeable in the interchromosomal (sap) regions of the nucleus. (Formalin fixed and stained in uranyl acetate. × 8,000)

found within the nucleolus (Fig. 3). Some of this material appears as extensions of the organizer chromatin and some is not so. Fig. 4 is a micrograph showing nucleolus and chromosomes after extraction first with pronase for 20 min and then with RNase for 2 h. The nucleolus is almost a negative image of the controls whereas the chromosomes are largely retained and dense, though with no discernible ultrastructure. In certain sections, such as that in Fig. 4 for example, small patches of chromatin-like material are seen dispersed in the nucleolus.

DNase extraction of glutaraldehyde-fixed cells causes variable decrease in the binding of uranium by chromosomes. After digestion of formalin-fixed cells for 90 min, however, the chromosomes contain numerous holes or empty spots as shown in Fig. 5. (DNase used with mg^{++} gives similar results in a shorter period.) It may also be noted that such holes occur within the nucleolus, which is otherwise unaffected by DNase. The size and distribution of the holes in the nucleolus correspond fairly closely to those of the intranucleolar chromatin patches observed after other procedures.

Extraction with trypsin for 30 min results in marked loss of chromosomal constituents (no figure presented).

A similar striking loss of constituents occurs confined to small spots up to 500 mμ within the inner region of the nucleolus; there is also a general extraction of the matrix material in the outer region of the nucleolus.

In a previous electron microscope investigation[5] in which osmium fixation was used, the electron density of all nuclear structures was uniformly high and no small patches of chromatin were detected within the nucleolus. With aldehydes as fixatives, a certain amount of distinctive staining of cellular components seemed possible and they have the added advantage of enabling specific extraction by enzymes. On these accounts, the present investigation was carried out on aldehyde-fixed glands.

In sections stained with uranyl acetate alone, the chromosomes and nucleoli were more or less uniformly stained. After the double-staining procedure described earlier, it was seen that the chromosomes were distinctively denser and this enabled small patches of chromatin-like material to be easily detected within the nucleolus. It has been pointed out before[6] that, after formalin and acrolein fixation, uranyl acetate at *p*H 5 stains the deoxyribonucleoproteins more intensely than the ribonucleoproteins, although the chemical basis of this distinctive contrast is not known. Earlier, Huxley and Zubay[7] had noted that pretreatment of lightly fixed (5 min in buffered osmium tetroxide) tissue with uranyl acetate seemed to render DNA-containing regions accessible to lead hydroxide which increased their density preferentially. On this basis they observed that some differentiation between DNA and RNA may be possible by comparison of "uranium–lead" and "lead only" stained tissues.

The investigations with enzymes have further served to elucidate the nature of the intranucleolar chromatin-like material. By successive digestions on same sections with pepsin and RNase in any order, it was shown how patches of chromatin occur within the extracted nucleolus. This procedure was observed by Bernhard and Granboulan[8] to be an effective method to demonstrate intranucleolar DNA. The intranucleolar chromatin is retained even when the nucleolar extraction is virtually complete, as when pronase is used instead of pepsin in the above procedure. In the present investigation the most indicative evidence of intranucleolar DNA comes from the digestion experiments with DNase. Extraction with trypsin also shows that, at the probable sites of intranucleolar DNA, proteins also are present as in chromosomes. All these experiments point to one conclusion, that is, that chromatin-like material occurs inside the nucleolus and this in all probability contains DNA.

Intranucleolar chromatin or DNA has recently been demonstrated in a few mammalian cells by electron microscope cytochemical procedures[2,6,8–13] and the present instance is the first from an insect cell. However, this approach to the problem has had such limited application so far that no generalization concerning intranucleolar DNA can be made yet. Based on light microscope cytochemical tests, there have been many reports (see review by Busch *et al.*[14]) of DNA inside the nucleolus, but some of these require confirmation and on the whole the tendency has been to view them with scepticism. Chemical methods of analysis have yielded a wide range of values for DNA in nucleolar fractions[14,15] and although a part of this in all cases may be due to contaminating chromatin, it would seem that not all the DNA can be dismissed as such. A definite solution to the problem of the intranucleolar DNA will probably come from concerted attempts by chemical methods and ultrastructural approaches.

Concerning the distribution of intranucleolar DNA it may be noted that most patches occur in that part described previously[5] as the inner homogeneous region. It was mentioned that some of the patches situated close to the organizer are apparently extensions of the organizer (Figs. 2–4), but the question of whether the smaller patches dispersed within the nucleolus are linked to each other or the organizer cannot be answered at present. This will be a laborious task as a considerable number of serial sections will have to be examined. In a mammalian cell, it has been shown[13] that the intranucleolar chromatin and the associated chromatin form a continuous system.

In future, if intranucleolar DNA proves to be of widespread occurrence, the mode of origin of this DNA will invite enquiry, but, for the present, this must remain in the realm of speculation. Apart from the obvious possibility of its extension from the organizer locus—the situation with regard to the DNA may be analogous to that in Balbiani rings—it may be asked if minute quantities of DNA (so far undetected) might find their way into the large organized nucleolus by way of prenucleolar bodies reported in the literature[16,17] (other references in Kopac and Mateyko[18]). From the manner of origin of similar bodies from within chromosomes, the possibility that certain of their constituent elements might contain DNA was raised before[19] and this hypothesis is now open to investigation in suitable material by methods of ultrastructural cytochemistry.

The search for intranucleolar DNA was made in the hope that the results would contribute to a better understanding of the functional aspects of nucleolus in *Smittia* investigated[1,20,21] by various experimental approaches. With regard to the nature of nucleolar RNA, it is generally held that the nucleolus is the site of synthesis of ribosomal RNA, and recent biochemical investigations show[22,23] that the DNA complements of ribosomal RNA are located in the organizer chromatin. The nucleolus of the salivary glands of late larval stage of *Smittia*, however, appears to be a site of synthesis of transfer RNA as well as high molecular weight (> 28*S*) RNA[24–28], and several indications point to the non-involvement of the nucleolar organizer in this process[1,20,21,29]. An implication of the present finding, therefore, is that in *Smittia* the intranucleolar DNA may be the primer for the RNAs synthesized in the nucleolus.

I thank Mr. M. D. McKean for technical assistance. I also thank Dr. W. Bernhard and colleagues for help with the methods of ultrastructural cytochemistry during my visit to their laboratory at Villejuif early in the course of this work. This work was supported by the British Empire Cancer Campaign for Research and the Damon Runyon Memorial Fund for Cancer Research.

REQUIREMENT FOR RIBONUCLEIC ACID SYNTHESIS FOR DEOXYRIBONUCLEIC ACID REPLICATION IN BACTERIA

By DR. C. O. DOUDNEY

Section of Genetics, Department of Biology, University of Texas, M.D. Anderson Hospital and Tumor Institute, Houston, Texas

A REQUIREMENT for protein formation for continued replication of deoxyribonucleic acid (DNA) in bacteria has been observed[1–8]. It has been proposed that the formation of protein at some point in the cycle of replication of the bacterial chromosome is necessary for continued DNA formation[6,7]. This proposal was based on the observation that blockage of protein synthesis in a bacterial culture leads to a cessation of DNA synthesis after that relative increase in quantity of DNA which would account for all chromosomes being replicated. The present article describes experiments which show that incubation in the absence of required amino-acids of an auxotroph of *Escherichia coli* which requires amino-acids and thymine, thus preventing protein synthesis, and at the same time preventing DNA synthesis during the incubation through the absence of thymine from the medium, leads to a requirement for ribonucleic acid (RNA) formation (but not for protein formation) if DNA synthesis is to continue to the end of the replication cycle. The results support the premise of a recent suggestion[9] that RNA is an essential component of the DNA synthetic system.

The techniques for measurement of nucleic acid and protein and the bacterial growth procedures have been described[10]. The organism used was *E. coli* strain *TAU-BAR*, an auxotroph requiring thymine, uracil, arginine, methionine, tryptophan and proline, and furnished to this laboratory by Dr. Phillip Hanawalt, of Stanford University. The supplementation of minimal growth medium was 8 μg per ml. thymine, 20 μg per ml. uracil, and 40 μg per ml. of the required L-amino-acids, except for L-tryptophan, which was 20 μg per ml.

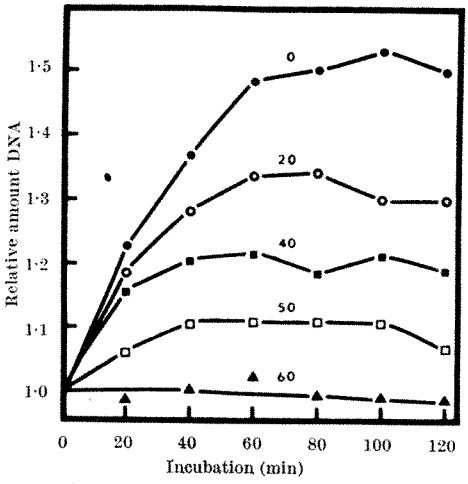

Fig. 1. Formation of DNA by *E. coli* strain *TAU-BAR* in medium lacking required amino-acids after different periods of incubation in medium lacking thymine and the required amino-acids. Log phase cultures of this strain were filtered rapidly on membrane filters, washed and re-suspended in minimal medium with all supplements except thymine, methionine and tryptophan. After incubation at 37° C for the period of time (in min) indicated by the number labelling each curve, thymine was added (zero incubation time) and incubation continued. A comparable effect was found with incubation in the individual absence of arginine, tryptophan or methionine (but not proline) but the combined absence of methionine and tryptophan proved most effective and was used in these investigations. The vertical axis is in units of 3·6 μg of DNA per ml. of culture. All incubations were at 37° C with vigorous aeration through rotary shaking

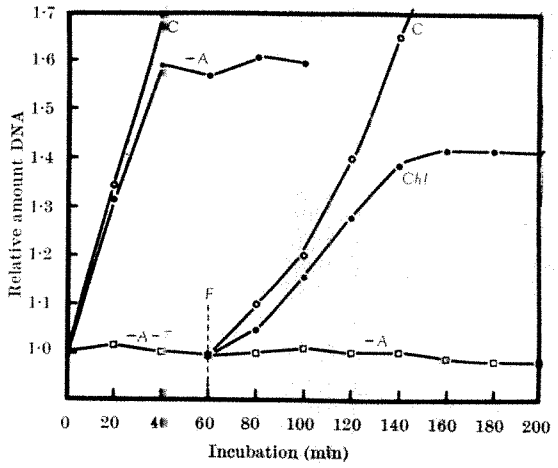

Fig. 2. Recovery of DNA synthesis by *E. coli TAU-BAR* after incubation for 1 h in the absence of thymine and required amino-acids. Log phase cultures of this strain were rapidly filtered, washed and re-suspended in warm medium lacking thymine, methionine and tryptophan (−*A*, −*T*) and incubated for 1 h (0–60 min). Control cultures were re-suspended in warm complete medium (*C*) and medium containing thymine but lacking methionine and tryptophan (−*A*). After 60 min incubation, the −*A*, −*T* culture is filtered, washed and rapidly re-suspended (in less than 2 min) in warm complete medium (*C*), complete medium to which chloramphenicol (40 μg/ml.) has been added (*Chl*), and medium lacking methionine and tryptophan (−*A*). In addition, the effect of incubation in medium lacking methionine and tryptophan, but containing thymine and chloramphenicol was determined (not shown). In this case relative DNA concentrations with incubation were: 60 min, 1·0; 80 min, 1·03; 100 min, 1·11; 120 min, 1·25; 140 min, 1·36; 180 min, 1·38. Units, 3·6 μg of DNA per ml. of culture

Incubation of strain *TAU-BAR* for increasing periods in medium which prevents DNA synthesis (through the absence of thymine) and RNA and protein synthesis (through the absence of amino-acids) leads to a progressive loss of capacity for subsequent DNA synthesis after addition of thymine (Fig. 1). Approximately 60 min of prior incubation under these conditions is necessary for complete loss of capacity to form DNA later in amino-acid-deficient medium containing thymine. If thymine and the required amino-acids are restored to the culture, DNA synthesis resumes (Fig. 2). The possibility exists that lack of cellular capacity for RNA synthesis under these conditions is involved in failure of DNA synthesis, since it has been shown that a deficiency in a required amino-acid leads to cessation of RNA synthesis[11]. The antibiotic, chloramphenicol, was utilized to determine whether RNA formation in the absence of protein synthesis would restitute the capacity for DNA replication with these cultures. It has been established that nucleic acid synthesis will proceed in the presence of this antibiotic, though protein synthesis is blocked[12,13]. While chloramphenicol blocks the formation of ribosomes, it allows formation of RNA to occur[14,15]. The expected increase in DNA in the absence of protein formation, assuming synthesis to the end of the replication cycle (or

an increase of approximately 40 per cent)[7], occurs in the presence of chloramphenicol (Fig. 2) and a relative increase in RNA approximately equal to the increase in DNA is seen (Table 1). No increase in DNA is observed in the presence of thymine when the absence of the required amino-acids is used to block RNA and protein synthesis (Fig. 2) and no formation of RNA or protein is observed (Table 1). That blockage of RNA synthesis and not some other effect of incubation without amino-acids is involved in the limitation of DNA synthesis observed is supported by the finding that addition of chloramphenicol to the culture in the absence of the required amino-acids leads to the recovery of DNA synthesis, as well as RNA synthesis. It has been shown that addition of chloramphenicol to a culture lacking an essential amino-acid endows that culture with the capacity for RNA synthesis[1,2].

Incubation without thymine and the required amino-acids does not lead to any observable breakdown of RNA during the first 60 min, but breakdown does occur after this time (Table 1). This RNA breakdown takes place whether or not thymine is re-added at 60 min of incubation. If thymine is present during the first 60 min of incubation without amino-acids, allowing the completion of the DNA replication cycle, little breakdown of RNA is observed, even with prolonged incubation without amino-acids with or without thymine. Apparently, completion of the DNA replication cycle endows the cellular RNA with an immunity to the RNA breakdown induced by incubation without amino-acids and without thymine. This compares with the finding of Maaløe and Hanawalt[6] that completion of the DNA replication cycle prevents the death of cells due to lack of thymine.

Table 1. RNA AND PROTEIN FORMATION BY *E. coli* STRAIN *TAU-BAR* AFTER INCUBATION WITHOUT THYMINE AND REQUIRED AMINO-ACIDS

Relative amount of RNA (*R*) or protein (*P*) with incubation

	Min:	60	80	100	120	140	160	180	200
C	*R*	1·00	1·14	1·21	1·30	1·42	1·65	2·21	2·43
	P	1·00	1·11	1·14	1·27	1·41	1·71	2·24	2·51
Chl	*R*	1·00	1·17	1·20	1·26	1·36	1·36	1·34	1·33
	P	1·00	0·95	0·95	0·90	0·90	0·93	0·88	0·88
−A	*R*	1·00	1·00	0·91	0·84	0·81	0·69	0·66	0·51
	P	1·00	1·03	1·00	1·00	0·94	0·97	0·97	0·94

For the first 60 min, the culture was incubated without thymine, methionine and tryptophan. It was then filtered, washed, and re-suspended in complete medium (*C*), complete medium containing chloramphenicol (*Chl*), or medium lacking methionine and tryptophan (*−A*). See the legend to Fig. 2 for details of this experiment. 1 unit is 22·0 μg of RNA and 65·3 μg of protein per ml. of culture.

These results suggest the possibility that incubation in the absence of required amino-acids and thymine results in some damage to the DNA (ref. 16) or to an RNA component of the DNA synthetic system[9]. This damage ultimately leads to a breakdown of cellular RNA in the absence of RNA formation. Incubation without RNA formation (that is, in the absence of required amino-acids) does not result in DNA replication because of the damage. If, however, incubation is under conditions where RNA formation takes place, the capacity to make DNA is recovered and DNA synthesis proceeds to the end of the cycle, where it is limited in chloramphenicol by the requirement for protein synthesis.

Kellenberger *et al.*[17] have shown in a "DNA stringent" strain of *E. coli* an increased short-term incorporation of radioactive thymidine, when chloramphenicol is added to cultures incubated in the absence of required amino-acids. They proposed that DNA is under the same control observed by Stent and Brenner[11] for limitation of RNA synthesis in the absence of required amino-acids. This appears unlikely in view of the fact that in most strains (including the one utilized here) DNA synthesis continues to the end of the cycle in the absence of required amino-acids and suggests that the results of Kellenberger *et al.*[17] may be explained by the requirement for RNA formation for subsequent DNA synthesis described here. Okazaki and Okazaki[18] observed with *Lactobacillus acidophilus* that DNA synthesis ceases in a manner comparable to *E. coli*[7] if amino-acids are deleted from the medium but the DNA content of the culture increases several-fold in the presence of chloramphenicol. These results may be understood if incubation without amino-acids leads to loss of the RNA required for continued DNA synthesis, while incubation with chloramphenicol allows retention of the required RNA and its participation in several rounds of DNA formation in this *Lactobacillus* strain. This interpretation would be compatible with these investigations on *E. coli* into the effect of incubation without amino-acids and incubation with chloramphenicol on DNA replication.

Doudney[8] has related the relative increase in RNA in cultures of an amino-acid-requiring strain (previously brought to the end of its replication cycle by starvation of an essential amino-acid) to subsequent relative increase in DNA and suggested the possibility that RNA formation on the DNA template is required "at the molecular or genetic level" for subsequent DNA replication. Hanawalt[19] has proposed that synthesis of complementary RNA normally precedes DNA replication, in explanation of the involvement of RNA synthesis in death due to lack of thymine. On the basis of investigations of the formation of RNA during the recovery of the DNA-synthetic system of bacteria damaged by ultra-violet light, we[9] have suggested that RNA is an essential component of the DNA-synthetic system in the unirradiated bacterial cell and that the requirement for RNA synthesis in DNA replication after exposure to ultra-violet light is in replacement of this ultra-violet-damaged RNA. Our investigation[9] suggested that the involvement of protein formation in initiation of the cycle of DNA synthesis may be indirect and dependent on the necessity of protein formation for continuation of RNA synthesis past the chromosomal origin (or some other site). The present investigations are in agreement with this suggestion and support the hypothesis that in *E. coli* each cycle of DNA replication is preceded by a cycle of RNA formation which may be effectively limited by a requirement for protein synthesis. This would explain the accumulation of capacity for more than one cycle of DNA replication under conditions of blocked DNA synthesis (that is, thymineless incubation[20,22], or incubation after ultra-violet exposure[21,22]) since it appears reasonable according to the aforementioned hypothesis that prior formation of RNA would effectively by-pass the limitation on DNA synthesis imposed by blockage of protein synthesis, initiating a new round of DNA synthesis[20].

We have observed that residual synthesis of DNA in the absence of required amino-acids exceeds the expected 40 per cent increase, which accounts for the chromosomes coming to the end of their cycle in a log phase culture[7] (Fig. 2). However, increase of DNA in chloramphenicol after incubation without amino-acids or thymine is only 40 per cent (Fig. 2). This could be explained if it is assumed that the "node" of RNA synthesis is normally somewhat in advance of the "node" of DNA synthesis. Thus, with withdrawal of the required amino-acids, DNA synthesis would proceed to the point which RNA synthesis has reached. In general, the distance along the chromosome between the site of RNA synthesis on the DNA template and the site of DNA replication would determine the residual capacity for DNA replication after limitation of RNA formation by any means, and this might be expected to vary in various strains and under various conditions. With a culture lacking in the RNA required for DNA replication because of incubation without thymine and the required amino-acids, synthesis of RNA and DNA in chloramphenicol would proceed only to the end of the cycle (the point where the requirement for protein formation limits RNA synthesis[9]) accounting for the 40 per cent increase.

This investigation does not determine whether the requirement demonstrated for RNA formation in DNA replication is indirect and supporting or whether the RNA

is actually involved in "information transfer" by way of complementary hydrogen bonding of purine and pyrimidine bases. The control of DNA replication by prior RNA formation appears to constitute an effective cellular mechanism for relating gene replication to previous cytoplasmic increase.

ELECTROPHORETIC SEPARATION OF SERUM ACID PHOSPHATASE ISOENZYMES IN GAUCHER'S DISEASE, PROSTATIC CARCINOMA AND MULTIPLE MYELOMA

By DR. ARTHUR F. GOLDBERG, DR. KINTOMO TAKAKURA and DR. ROBERT L. ROSENTHAL

Department of Hematology and Research Institute for Skeletomuscular Diseases of the Hospital for Joint Diseases and Medical Center, and Department of Medicine, New York University School of Medicine, New York

PATIENTS with Gaucher's disease[1], prostatic carcinoma[2] and multiple myeloma[3,4] may have elevated serum acid phosphatase activity. In a search for characteristic isoenzymes, sera from normal individuals and patients with these diseases were investigated by disc electrophoresis on polyacrylamide-gel columns[5]. These columns were later stained for acid phosphatase activity by the method of Barka[6].

Electrophoresis was performed (1 m.amp, 100 V) for 2 h at 4° C. The test serum (25 μl.) was directly layered on the spacer gel while it was beneath the buffer. (Anti-convection gel was not added, as is sometimes the case, to increase the amount of serum subjected to electrophoresis.) After separation, columns were fixed in 10 per cent neutral formalin-acetate (NFA) for 30 min at 4° C and then briefly rinsed in cold distilled water. Columns were later stained for 12–24 h (4° C) using Barka's azo-dye method with naphthol *AS-BI* phosphate as substrate (*p*H 5)[7]. After incubation, the columns were rinsed and stored in test-tubes containing distilled water. Zones containing acid phosphatase activity stained bright red while albumin stained non-specifically a light yellow (Fig. 1).

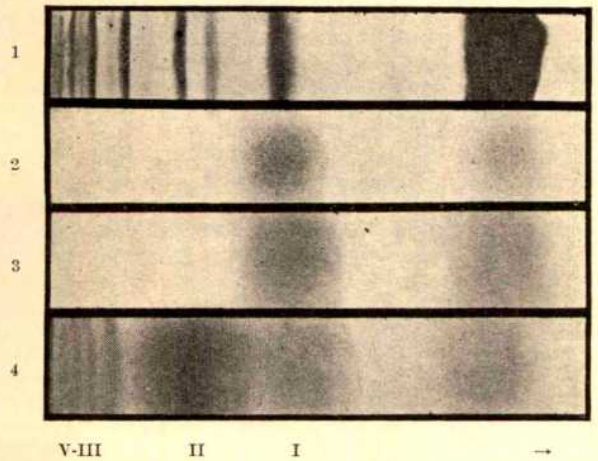

Fig. 1. Normal serum protein electrophoretic pattern in polyacrylamide-gel column (1) compared with electrophoretic pattern of acid phosphatase activity in normal (2), prostatic carcinoma (3), and Gaucher's disease patients (4). Isoenzyme bands are labelled I–V. Acid phosphatase activity stains red while albumin is non-specifically coloured a light yellow

Fixing the acrylamide gels with NFA before the histochemical procedure minimized background staining and retarded diffusion of the enzyme during incubation. No major decrease in the intensity of the stained isoenzyme patterns occurred after fixation in normal individuals or diseased patients. Electrophoresis of haemolysates of normal red blood cells was performed and stained for acid phosphatase activity. If the columns were fixed in NFA (30 min) after electrophoresis and before the histochemical treatment, no enzyme activity of erythrocytic origin was observed, thus confirming the observation that red blood cell acid phosphatase is inhibited by formalin[8].

Gel columns which contained electrophoretically separated serum were boiled in distilled water (100° C, 10 min) to destroy enzyme activity and then stained for acid phosphatase activity. No enzyme activity was demonstrated. The Gomori method[9] was tried as a histochemical procedure and found unsuitable. Specific zones of enzyme activity could not be differentiated from a similarly stained background.

Acid phosphatase activity in controls (six males and eight females) with normal serum acid phosphatase activity had one broad red staining band on electrophoresis which migrated about midway between the origin and the albumin fraction (Fig. 1, No. 2). No sex difference was observed.

Five of six patients with prostatic carcinoma investigated had increased total serum acid phosphatase activity (1·5–4 Bodansky units—B.U.) (normal 0–1). The sixth patient had a serum acid phosphatase of 0·9 B.U. All patients exhibited only one staining band which migrated similarly to normal acid phosphatase (Fig. 1, No. 3). All carcinoma patients had considerably increased staining compared with normals. The intensity of this reaction product was proportionate to the total serum acid phosphatase level.

The columns of prostatic carcinoma patients which were treated with tartrate solution (0·1 M, 30 min) after electrophoresis and before enzyme staining had the acid phosphatase activity in Band I markedly, but not completely, inhibited compared with its untreated control. Negligible inhibition occurred in similarly treated normal serum.

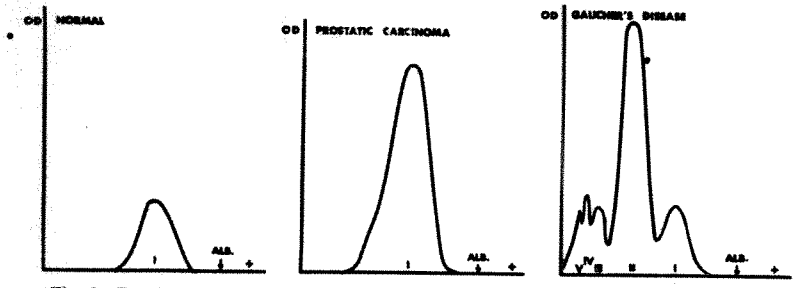

Fig. 2. Densitometric tracing of electrophoretic serum acid phosphatase pattern in polyacrylamide-gel column in normal, prostatic carcinoma, and Gaucher's disease

Nine patients with Gaucher's disease (six males and three females) had elevated serum acid phosphatase values (8–25·8 King-Armstrong units) (normal 1–4). All had at least two enzyme bands (Fig. 1, No. 4). Band I migrated similarly to that of normal patients. Band II was the broadest and most intensely stained. Other minor bands (III, IV, V) were considerably narrower and found in five of the nine patients. Of these five patients, three had three bands while two patients had two minor bands. Compared with the serum protein electrophoretic pattern[5,11] (Fig. 1, No. 1), Band I migrated in a position similar to transferrin. Band II was in the fast moving haptoglobulin region while Bands III, IV, and V had mobilities of gamma globulins and the slower haptoglobins. No differences were observed between male and female. In one family, a male with Gaucher's disease had five isoenzyme bands. His apparently normal parents, sister and her two daughters had normal electrophoretic patterns and serum acid phosphatase activity.

A semi-quantitative estimate of the amounts of acid phosphatase was made by passing the stained column through a densitometer ('Chromoscan *J*288', Joyce Loebl and Co.). Variations in the quantity and difference in the isoenzyme pattern of a normal individual compared with a patient with prostatic carcinoma and another with Gaucher's disease are illustrated (Fig. 2).

Sera from six patients with multiple myeloma which exhibited normal total serum acid phosphatase activity (B.U.) exhibited one electrophoretic band which migrated similarly to the normal controls. This band stained with normal or slightly less than normal intensity. Four patients had hypogammaglobulinaemia and two had a monoclonal spike migrating in the beta region on protein electrophoresis.

Tissue from a human plasmocytoma and from an experimentally induced mouse plasmocytoma[10] were examined for acid phosphatase activity. Each tumour was homogenized with two volumes of 0·25 M sucrose (4° C). A portion of the centrifuged supernatant (4° C, 105,000*g*, 90 min) diluted to ten times the original tumour weight with 0·25 M sucrose was subjected to disc electrophoresis and stained for acid phosphatase activity. Two isozyme bands were observed in the human plasmocytoma homogenate. The faster one migrated just behind Band I while the slower component was in the haptoglobin region. One band was demonstrated in the mouse plasmocytoma homogenates which migrated in a similar fashion to the first band of human myeloma tissue.

Only a very small number of normal individuals and those with prostatic carcinoma have had their sera electrophoretically examined for isoenzymes of acid phosphatase. Earlier electrophoretic investigations on paper[12,13], in starch gel[14–16] and starch block[17] demonstrated one enzyme zone in normal and prostatic carcinoma patients. In contrast, Dubbs and Hilburn, also using a starch-gel medium, found three isoenzyme fractions in normal individuals[18]. Naiman and Oski described a distinctive pattern on starch-gel electrophoresis in prostatic carcinoma patients, but were unsuccessful in demonstrating serum acid phosphatase isozymes in normal individuals[18]. While our investigations were in progress, Czitober *et al.*[20], using starch gel electrophoresis, also reported three isoenzyme zones in normal subjects and found four in prostatic carcinoma. In all these reports[12–20] different enzyme staining techniques were used. The reported differences observed in the number, width and migration of acid phosphatase isoenzymes in the normal and pathologic sera may be related to the specificity of the various enzyme-staining methods and substrates used as well as to the different electrophoretic techniques[21].

Normal serum acid phosphatase is reported to be composed mainly of platelet acid phosphatase[22], and this isoenzyme is not significantly inhibited by tartrate[22,23]. Prostatic acid phosphatase, however, is sensitive to tartrate[2,8]. The marked reduction in the staining of the enzyme band in all our prostatic carcinoma cases which were treated with tartrate confirms the prostatic origin of this enzyme component. This phenomenon was also evident in the patient with a normal total serum acid phosphatase. This inhibition procedure was of diagnostic value in a fashion similar to differential serum enzyme investigations of prostatic acid phosphatase[2].

The three patients with Gaucher's disease investigated by Czitober *et al.* were reported to have five acid phosphatase fractions; however, this is not quite clear from their drawing[20]. The fact that some of our patients did not have any or all of the minor acid phosphatase bands (III, IV, V) suggested that these isoenzymes might arise from some organ, for example, spleen, liver or bone, or perhaps represent intrinsic molecular differences in the disease itself. It was found that the four patients who had no minor bands had all undergone splenectomy. These findings suggest that the spleen may directly or indirectly be the source of certain serum isozymes. The two individuals with only two extra bands were our youngest patients (17- and 23-year-old males). The ages of the three persons with three minor bands (two males and one female) ranged from 30 to 54. All had enlarged spleens palpated 3–9 cm below the right costal margin. Although less splenic enlargement was found in those with two minor bands, one patient with three bands also had a smaller-sized spleen.

The role of acid phosphatase activity in Gaucher's disease is unknown. The increased amounts and differences in isoenzyme pattern in this disease compared with normal suggest that the basic abnormality in this illness is not only restricted to disturbed cerebroside metabolism. In a search for some inherited abnormality in the absence of apparent Gaucher's disease, the relatives of one patient were investigated and no extra isoenzymes were observed.

Although Band I migrated at essentially the same position in normals, prostatic carcinoma, myeloma and Gaucher's disease patients, slight differences in migration were nevertheless present (Fig. 1). This further suggests intrinsic differences among these isoenzymes.

Although the cells of multiple myeloma contain considerable acid phosphatase activity[3,4,7,24] like the Gaucher cell[25], elevated serum enzyme-levels are most unusual[3,26]. They were not increased in the cases investigated. The elevated serum enzyme values in one case[4] may be secondary to obstructive phenomena due to infiltrating myeloma cells in the prostate itself or to the associated renal insufficiency[27] or both, rather than represent a primary sign of multiple myeloma. The possibility of specific serum isozymes originating from myeloma tissue or associated with this disease cannot, of course, be excluded from our data.

We thank Mrs. Myrna Lewis for her technical assistance and the staff of the Department of Urology, New York

University School of Medicine, for permission to investigate their patients with prostatic carcinoma.

IN VIVO FIBRINOLYSIS WITH A DIALYSABLE CONSTITUENT OF RECALCIFIED HUMAN PLASMA CLOTS AND GLUCONATE

By PROF. PAUL H. KOPPER
Biology Department, Washburn University, and Stormont-Vail Hospital, Topeka, Kansas

Two kinds of fibrinolysin are known to occur in the body: one is a proteolytic enzyme, plasmin, which attacks fibrin and fibrinogen as well as other proteins and amino-acid esters; the other acts solely on fibrin and seems to arise from the vascular endothelium in response to great stress such as severe exercise, electroshock, and injection of pyrogens, and in sudden death. The role of this second substance has been suggested to be merely activation of the enzymatic precursor plasminogen to plasmin[1], but the evidence is not conclusive. Despite a high level of this activator, plasminogen and plasmin concentrations in plasma have generally been found unchanged. This has been attributed to a potent plasmin inhibitor in plasma, antiplasmin. It has been claimed that only the plasminogen of the fibrin clot itself could be converted into functional plasmin by adsorbed activator. However, definite proof for this contention, such as demonstration of differences between plasminogen and plasmin contents of plasma before clotting and of lysed fibrin, is still lacking.

In 1962, I reported[2] the ability of a strain of *Streptococcus faecalis* grown in human serum or on beef brain heart infusion agar to form a fibrinolytic metabolite in the presence of sodium gluconate. Fibrin heated to 85° C, to destroy plasminogen, was actually more readily decomposed than unheated fibrin, leaving no doubt that the agent under study was a true fibrinolysin rather than an activator. Later, an apparently identical basic substance was shown to occur[3] in the extracts of recalcified human plasma clots, obtained by their decomposition in distilled water at 5° C over a period of several weeks. The dialysate of such extracts could again be converted into a fibrinolysin by the bacteria in the presence of gluconate.

To speed up the preparation of extracts, plasma clots, retracted and washed repeatedly, were digested with crystalline trypsin at 37° C overnight. The centrifuged digest was dialysed three times for 24-h periods against distilled water. The dialysates were dried at 37° C and then extracted with a mixture of methyl alcohol and distilled water in the proportion of 2 to 1. Following centrifugation, the supernatant was dried again, leaving a brown amorphous material. It was weighed and dissolved in water to make a 10 per cent solution. The residue in the bag was precipitated with two volumes of methyl alcohol, and the dried supernatant treated like the dialysate. More of apparently identical material was recovered, but some turbidity remained in aqueous solution. In later preparations dialysis was omitted, and the final solution passed through a Seitz filter to clear it. Its ultra-violet spectrum showed a distinct pattern with a maximum at 275 mμ and a minimum at 247 mμ. The yield per 100 ml. of clotted human plasma was 100–150 mg; with bovine plasma it was 200–300 mg. Human serum turned out to be an even richer source of the material. Precipitated serum proteins, after digestion with trypsin, drying and extraction with 66·7 per cent methyl alcohol, yielded about 2–3 g per 100 ml. of serum.

In vitro, none of the preparations displayed fibrinolytic activity with or without sodium gluconate.

Cats and dogs were used in *in vivo* experiments. They were anaesthetized with sodium pentobarbital (25 mg/kg). To produce blood clots in the jugular veins of animals, a modified Wessler technique[4] was first tried. A vein segment is clamped off, and a small amount of serum is injected into it with a 30-gauge needle. However, the clots formed by this method were usually too small to obstruct the blood vessel. A different technique proved more satisfactory in our hands. Blood was expressed from a portion of the external jugular and the external maxillary veins above and below their juncture in the upper part of the neck, and 45-mm seraffine clamps (A. H. Thomas and Co., Philadelphia) were applied. From a superficial leg vein 1 ml. of blood was withdrawn and kept in a glass syringe for half the clotting time, previously determined. A sufficient amount to produce bulging of the jugular vein was injected into it above the point of confluence of the two veins; this varied from 0·4 to 0·7 ml. A clamp was immediately placed below this point, and the two clamps compressing the veins above it were removed, whereon they were flushed with saline to prevent blockage through clotted blood. Clots of a given size could thus be formed. They were generally made 100 mm long. A ligature narrowing the lumen of the vessel to about half its normal size was placed below the proximal clamp, and the two clamps confining the clot were released. In some experiments the vein, instead of being ligated, was pinched off with a clamp just enough to prevent escape of the clot. The clot acted as a haemostat; the vein below it was free of blood. A catheter was inserted into the jugular vein above the clot. When fluid was administered through it, blood flow was reversed in the medial external maxillary vein for the short distance between the jugular and the hyoid venous arch, leading to the veins of the opposite side. A clamp was placed above the point of insertion in experiments in which the clot was to be exposed to the

infused material alone; without the clamp, infusion mixed with blood would pass the clot. In systemic experiments the catheter was inserted in the opposite external jugular vein in the lower part of the neck.

Solutions infused were physiological saline and sodium gluconate in concentrations of 1, 5 and 10 per cent with or without 0·5 per cent of fibrin extract. They were administered at the rate of about 1 ml. per min locally and about 2 ml. per min systemically.

Clot dissolution was determined by angiography with 50 per cent sodium diatrizoate ('Hypaque'). The radio-opaque dye was injected before the start of the infusion and as soon as changes in the size and consistency of the clot became noticeable. This was usually accompanied by an observable restoration of blood flow below the ligature. Occasionally the vessel lumen was made too narrow, and even a shrunken clot would continue to obstruct it; however, such a clot was readily dislodged by the pressure of injected dye.

Experimental results were consistent. No clot dissolution was observed 30 min after infusion above the clot of 40 ml. of saline with or without fibrin extract, mixed with blood, or of 40 ml. of 1 per cent sodium gluconate without blood. Blood clots were broken down partially by direct infusion of 40 ml. of 1 per cent or 20 ml. of 5 per cent sodium gluconate with blood or of 40 ml. of 1 per cent sodium gluconate and 0·5 per cent fibrin extract without blood.

In systemic experiments, carried out in dogs weighing 8–11 kg, 95–125 ml. of 5 per cent or 50–60 ml. of 10 per cent sodium gluconate were required for partial clot decomposition. Clot breakdown seems to be limited to a small local area in direct contact with the vascular endothelium. This is illustrated in Fig. 1.

Even 24 h after an infusion parts of a clot too large to pass the narrowed lumen were still clearly visible in X-ray pictures. Likewise, small free-floating clots, produced in some experiments, remained unchanged regardless of the amount and nature of the infused solution. In practical application this should cause no difficulty since remnants of clots could be expected to pass to ever narrower blood vessels, finally to disappear completely.

An opportunity presented itself to test the effect of gluconate in an animal suffering from a severe thrombotic condition. In a mare, weighing 450 kg, a large blood clot was palpated at the bifurcation of the aorta. At the time of treatment the thrombus was at least 2 weeks old; the animal experienced great difficulty in standing and walking on its hindlegs, and some muscular necrosis, as evidenced by flaccidity, had set in. Three hundred g of sodium gluconate in 1·5 l. of distilled water were administered through the jugular vein over a period of 2 h. Even before termination of the infusion marked changes were observed in the behaviour of the animal. First there were muscular tremors, starting in the flaccid muscles, spreading to the muscles of the hindquarters and eventually of the entire body. As they subsided, profuse perspiration began. Within a few hours the horse appeared normal. It has now had full use of its hindlegs for about 4 months.

The systemic administration of considerable amounts of sodium gluconate was found to produce a temporary increase in the bleeding time of infused animals but left their clotting time unaffected. The appearance of cadaver fibrinolysin is likewise associated with enhanced blood vessel wall permeability[5], both being manifestations of the shocked state. Locally, such a change in blood vessel walls is a common feature of inflammation. The limited fibrinolytic reaction in the obstructed vein would seem to be comparable with an inflammatory focus in the skin. Intradermal injection of 5 mg of fibrin extract with or without 5 mg of gluconate, but not of gluconate alone, into albino rabbits invariably produced some reaction, which became more distinct in the presence of a suitable adjuvant. Without gluconate the predominant feature was oedema with induration, with gluconate pronounced erythema, occasionally with incipient haemorrhage. When fibrin extract mixed with 50 μg of epinephrine was injected into the skin, haemorrhagic necrosis resulted. Thus far, only bacterial endotoxins have been reported to have this specific effect with epinephrine[6]. However, it has already been suggested[7] that these metabolites might in fact elicit the formation of other substances by the body.

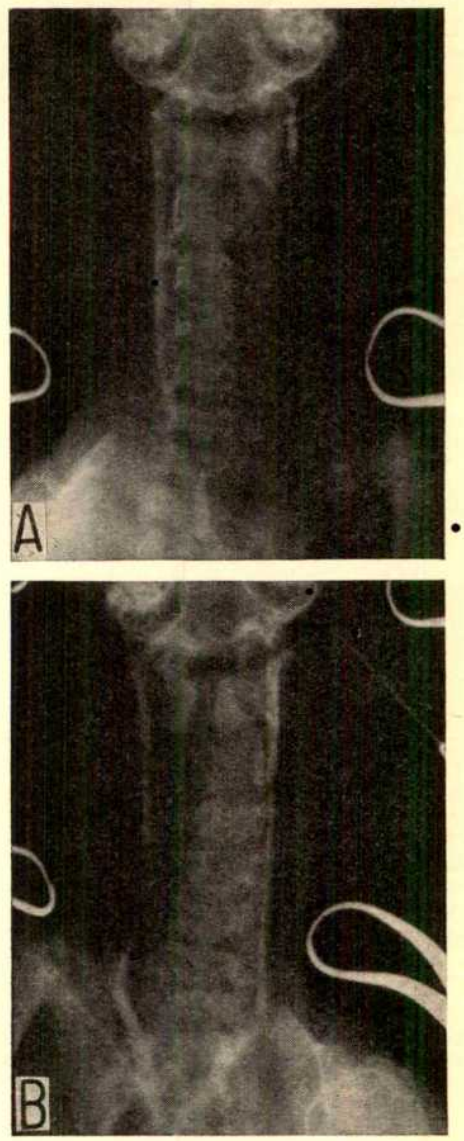

Fig. 1. Partial lysis of a blood clot in the jugular vein of a cat. *A*, Left jugular vein completely obstructed, with clear space above the clot. *B*, Circulation re-established. Central core of the clot is left behind and has been swept back by pressure of the injected dye

This work was supported in part by a grant from the Kansas Heart Association. I thank Dr. H. R. Michaux, Dr. S. M. Teeter and Mr. D. L. Nelson for their valuable help in the animal experiments and the Morris Research Laboratories, Topeka, for the use of their facilities.

NUCLEATION BY ELASTIN

By DR. ALBERT E. SOBEL*, STANLEY LEIBOWITZ, DR. RALPH G. EILBERG and DR. FRANCOIS LAMY

Joseph and Helen Yeamans Levy Laboratories, Beth Israel Hospital, New York City, and Department of Anatomy and Cell Biology, Pittsburgh University School of Medicine, Pittsburgh, Pennsylvania

A FUNDAMENTAL step in the process of mineralization is the formation of nuclei of crystal growth. In this connexion, the isolation of substances that can induce nucleation is basic to the understanding of calcification in living organisms. As a result of the interest directed toward the calcification of bone, collagen has been identified as a substance capable of inducing the formation of nuclei of hydroxyapatite crystal growth from a metastable solution[1-8]. Mineralization occurs, however, in many areas other than bone. Among those investigated by our group, in addition to collagen, are: rat tail tendon, rat and rabbit aorta, epiphyseal cartilage, inorganic salts, saliva extract, bovine submaxillary mucin and elastin[9-14]. It is of interest to investigate these systems, as new calcifying catalysts are being discovered as a result[13,14].

This communication presents evidence indicating that purified elastin is capable of inducing the formation of nuclei of hydroxyapatite crystal growth.

Evidence that elastin can be the site of calcification was shown by Lansing[15], using the optical microscope and histochemical investigations. Electron microscope investigations on the calcification of the aorta conducted by Eisenstein and Zeruolis[16] confirmed this. Yu *et al.* supplied additional information that calcification of human aorta is in the elastic fibre within the limiting membrane of the fibre which forms a continuous phase with attached collagen fibres[17]. Ayer[18] has prepared electron micrographs of calcium in elastic lamellae in addition to deposits in ground substances and in association with collagen in human aged arterio-sclerotic aorta.

Calcification *in vitro* investigations of the aorta by Eichel *et al.*[19,20] suggested that elastin might be involved in the induction of calcification *in vitro* of aorta. Later, Martin *et al.*[21] showed by electron microscopy the site of calcification *in vitro* to be elastin.

In February 1963, Dr. F. Lamy, of the University of Pittsburgh, provided Dr. A. E. Sobel with samples of purified elastin. It was possible to demonstrate that this material induced calcification *in vitro*. Confirmation of this was supplied, at the request of Dr. Sobel, independently by Dr. B. Sherman of the State University of New York, Downstate Medical Center, and Dr. R. Eilberg of the Colgate Palmolive Research Laboratories, New Brunswick, New Jersey.

In the same year, Taves and Neuman[22] suggested that elastin rather than the predominant collagen is responsible for the nucleation by acid-extracted tail tendon supplied by 'Sigma'. They supported their contention by demonstrating that a tissue rich in elastin (ligamentum nuchae) induced nucleation. Schiffmann *et al.*[23] also reported that bovine ligamentum nuchae extracted with phenol at 25° C induced calcification *in vitro*.

Two objections may be raised to the investigations of Taves *et al.*[22] and Schiffmann *et al.*[23]: (1) that the material used was a heterogeneous mixture, and (2) that tests to exclude the existence of inorganic seed crystals were not carried out. From our investigations we have evidence to indicate that acid-extracted rat tail tendon, collagen (Sigma), apparently similar to that used by Taves and Neuman is already pre-nucleated[24]. One billion (10^9) nuclei of hydroxyapatite (seed crystals) $25 \times 50 \times 100$ Å weigh only 4×10^{-4} μg and thus will escape detection by the usual chemical methods, but can be detected by other means recently developed[24]. In the presence of pre-existing nuclei (seed crystals) calcification represents crystal growth and does not provide rigorous evidence for the existence of an organic compound(s) capable of inducing nucleation.

In the present investigations several different batches of purified elastin prepared from ligamentum nuchae were used. The elastin was prepared by the modified method of Lamy *et al.*[25]. The amino-acid composition of this elastin is given in Table 1. The last three entries in Table 1 represent ninhydrin-positive peaks which do not correspond to any of the thirty standard amino-acids. They appear between ammonia and lysine and have been observed by others. Desmosine and isodesmosine have been described by Partridge *et al.*[26,27]. Because of its position in the chromatogram the compound listed as ornithine probably corresponds to another amino-acid described in a preliminary fashion by Franzblau *et al.*[28] as X^4.

Table 1. AMINO-ACID COMPOSITION OF ELASTIN

Amino-acid residues	Amino-acid residues (g/100 g elastin)	Amino-acid residues	Amino-acid residues (g/100 g elastin)
Cysteic acid	0·162	Leucine	9·249
Aspartic	0·606	Tyrosine	1·697
Methionine sulphone	0·040	Phenylalanine	5·574
Threonine	0·743	Ammonia	0·449
Serine	0·797	Lysine	0·400
Glutamic	2·263	Histidine	0·043
Proline	12·306	Arginine	0·820
Glycine	27·409	H-Proline	0·849
Alanine	17·974	'Desmosine' (refs. 26 and 27)	2·660
Valine	12·994	'Isodesmosine' (refs. 26 and 27)	3·840
Isoleucine	2·409	'Ornithine' (ref. 28)	0·211
		Total	98·495

4 mg of elastin were placed for 24 h in 30 ml. of calcifying solution similar to those which were used in our earlier investigations for calcification *in vitro* of hypertrophic epiphyseal cartilage of saliva extract and collagen[1,5,6,8,13]. Thymol was added at a level of 10 ml. per l. The calcifying solution contained (per l.): 70 mmoles sodium chloride, 22 mmoles sodium bicarbonate and 5 mmoles potassium chloride. Calcium was added as calcium chloride. Phosphate phosphorus was added as a mixture of sodium dihydrogen phosphate and sodium monohydrogen phosphate (4 : 1).

The calcifying solution containing the basal salts (sodium chloride, sodium bicarbonate, potassium chloride) and phosphate were acidified (and made oxygen free) by passing in carbon dioxide until a *p*H of 6·0–6·1 was reached. Calcium was then added and made up to volume. In the presence of the electrodes of a *p*H meter, nitrogen was passed through the solution until a *p*H of 7·28–7·30 was reached. The solutions containing the samples and controls were then incubated at 37° C for 24 h or 48 h, depending on the investigations, after which time equal portions of the supernatant were taken for analyses.

The amount of calcium and phosphate incorporated was measured by the change in supernatant liquid using the methods previously used in similar investigations[2,5,6].

* Present address: University of Pennsylvania, The Graduate Hospital, Department of Biochemistry, Philadelphia, Pennsylvania.

Some of the control solutions were kept at least 24 h longer than the sample investigation, and if any precipitate developed the experiment was considered invalid. If the experimental solutions were in any way turbid, the experiment was discarded.

The first investigations indicated that the elastin prepared by Dr. Lamy induced calcification within the elastin body with the formation of hydroxyapatite (courtesy of Dr. A. Hirschman). However, nitrous acid treatment which inactivates nucleation by saliva extract, treatment with boiling water which inactivates rachitic cartilage and bovine submaxillary mucin, and treatment for 24 h with 20 mmoles cupric chloride in methanol or water which inactivates various collagens and saliva extract had no effect on the ability to calcify untreated elastin. These treatments do not inhibit crystal growth of pre-existing hydroxyapatite nuclei[8,12–14,24].

Thus we were confronted with the problem that the treatments which inactivate the nucleating ability of various nucleating catalysts do not inactivate the nucleating ability of elastin or the elastin that is already nucleated (that is, contains inorganic seed crystals). In this connexion, it must be borne in mind that pre-existing nuclei (seed crystals) of hydroxyapatite crystal growth may be due to inorganic substances other than calcium phosphates[12,29,30].

To remove inorganic seed crystals, we extracted 4 mg elastin with 25 ml. of 0·1 N hydrochloric acid in methanol for 3 days with vigorous shaking. This was followed by exhaustive washings with 50 per cent methanol and then triple-distilled water. The washing was continued until the extract was free of chloride ions. The elastin was then covered with solutions used for calcification *in vitro* and stoppered—care was taken to exclude all visible gas space. The supernatant was removed and the samples washed with triple-distilled water and fresh calcifying solutions were added for an additional 24 h when necessary.

Cupric chloride had no inhibiting effect on purified elastin unless it was specially treated in advance (Table 2). This finding can be compared with the results given in Table 3 in which there is no uptake of calcium or phosphorus after 24 h when acid extracted elastin is treated with 20 mmoles/l. of cupric chloride in methanol. However, it would seem that this situation is reversible after calcification for an additional 24 h.

The cupric chloride has no effect on the calcification *in vitro* of 'nucleated' elastin as can be seen from Table 4.

Table 2. INFLUENCE OF CUPRIC CHLORIDE ON THE CALCIFICATION *in vitro* OF UNTREATED ELASTIN, CALCIUM × PHOSPHORUS = 15 × 5 MG PER CENT²

Specimen	Centrifuged supernatant solution Calcium (mg per cent)	Phosphorus (mg per cent)
Control solution	14·9	4·64
Control solution	14·8	4·92
Control solution	14·9	4·76
Untreated elastin	8·1	2·2
Untreated elastin	7·4	2·1

Elastin* + 24 h, cupric chloride 20 moles/l. in methanol	8·4	2·3

* Untreated elastin.

Table 3. INFLUENCE OF CUPRIC CHLORIDE ON CALCIFICATION *in vitro* OF ELASTIN EXTRACTED WITH 0·1 N HYDROCHLORIC ACID IN METHANOL FOR 5 DAYS

Sample	Centrifuged supernatant solution Calcium (mg per cent)		Phosphorus (mg per cent)	
	24 h	48 h*	24 h	48 h*
Control solution	15·1	14·7	5·2	4·8
Control solution	14·9	14·9	4·9	5·0
Ext. elastin	8·1	7·4	1·86	1·61
Ext. elastin	8·3	7·9	1·84	1·70
Ext. elastin + 24 h, cupric chloride 20 moles/l. in methanol	14·3	8·26	4·68	1·89
Ext. elastin + 24 h, cupric chloride 20 moles/l. in methanol	15·2	10·6	4·8	3·6
Ext. elastin + 24 h, cupric chloride 20 moles/l. in methanol	15·4	12·1	5·0	4·0
Ext. elastin + 24 h, cupric chloride 10 moles/l. in methanol	7·6	7·4	2·2	1·8
Ext. elastin + 24 h, cupric chloride 10 moles/l. in methanol	8·3	7·6	2·0	1·9

* New calcifying solution after end of 24 h.

Table 4. INFLUENCE OF CUPRIC CHLORIDE ON CALCIFICATION *in vitro* FOR 24 H OF 'NUCLEATED' ELASTIN AND HYDROXYAPATITE ($Ca_3(PO_4)_2$)

Sample	Centrifuged supernatant solution Calcium (mg per cent)	Phosphorus (mg per cent)
Control solution	14·8	4·9
(calcium × phosphorus = 15 × 5 mg%²)	14·9	4·8
	14·7	4·8
	15·1	4·9
Elastin	10·5	2·4
	9·9	2·2
'Nucleated' elastin	10·1	2·8
+ 20 moles/l. cupric chloride in methanol, 24 h	10·6	2·9
$Ca_3(PO_4)_2$ + 20 moles/l. cupric chloride in methanol, 24 h	9·0	2·2
	9·1	2·2
$Ca_3(PO_4)_2$ + 20 moles/l. cupric chloride in water, 24 h	9·3	2·3
	9·0	2·1
$Ca_3(PO_4)_2$ + methanol, 24 h	8·5	1·6
	7·8	1·8
$Ca_3(PO_4)_2$ + water, 24 h	8·0	1·6
	8·1	1·8

Elastin was extracted for 3 days in 0·1 N hydrochloric acid in methanol. 'Nucleated' elastin was extracted elastin calcified *in vitro* for 24 h.

This table also indicates that when seed crystals of ($Ca_3(PO_4)_2$) are treated with 20 mmoles/l. of cupric chloride they are not prevented from inducing precipitation of the calcifying solutions.

The minimum calcium × phosphorus product at which nucleation occurs in acid-extracted elastin is 60 mg per cent² after 24 h. When 48 h have elapsed, the calcium × phosphorus product necessary for nucleation is lowered to 50 mg per cent². Unextracted and nucleated elastin calcify at an even lower product (40 mg per cent²; Tables 5 and 6), which again shows that once a substance becomes nucleated, it continues to calcify at a lower calcium × phosphorus product than is required for nucleation[8,12,13,24].

Table 5. MINIMUM CALCIUM × PHOSPHORUS PRODUCT FOR CALCIFICATION *in vitro* OF EXTRACTED AND UNEXTRACTED ELASTIN

Sample	Initial calcium + phosphorus (mg per cent)	Centrifuged supernatant solution calcium (mg per cent) 24 h	48 h*	phosphorus (mg per cent) 24 h	48 h*

Ext. elastin		3·9	4·1	5·0	5·0

* Elastin was first extracted for 3 days with 0·1 N hydrochloric acid in methanol.
† New calcifying solution after end of 24 h.
‡ 'Nucleated' elastin was obtained by preliminary calcification *in vitro* of extracted elastin for 24 h.

The results indicate the importance of testing for pre-existing nuclei before proposing that a substance is capable of inducing the formation of nuclei, and show that purified elastin is a nucleating substance. It can therefore be proposed that certain configurations of elastin may play some part in pathological calcification in aorta, skin and other sites in the body. The role of elastin in the

nucleation of bone (and dentine) needs to be further explored, as some elastin is present in bone[31].

CARBONIC ANHYDRASE DEFICIENCY WITH PERSISTENCE OF FOETAL HAEMOGLOBIN: A NEW SYNDROME

By DR. LIE-INJO LUAN ENG

Haematology Unit, Department of Medicine, and The G. W. Hooper Foundation, University of California San Francisco Medical Center, San Francisco, California

AND

DR. ROBERT TARAIL

Department of Medicine, Veterans Administration Hospital, Martinez, California

BETA-THALASSAEMIA major as well as hereditary persistence of foetal haemoglobin are characterized by marked elevation of foetal haemoglobin. Beta-thalassaemia major is associated with severe anaemia, while hereditary persistence of Hb F is not. In both conditions there is no carbonic anhydrase deficiency[1,2].

We now report on a syndrome in a 47-year-old Greek male, whose pattern of synthesis of haemoglobin and erythrocytic carbonic anhydrase resembled that of a new-born infant, namely, pronounced increase of Hb F, an extremely low level of Hb A_2 and a substantial carbonic anhydrase deficiency. The patient was non-anaemic but had red cell anisocytosis and poikilocytosis, target cells, circulating normoblasts, and abnormal and immature white blood cells in the bone marrow. He had hepatosplenomegaly and suffered from weakness, tendency to muscle cramps, evanescent dermal lesions, night sweats and episodes of partial loss of vision.

Analysis of his haemolysate by starch-gel electrophoresis[3] using various alkaline buffers revealed the presence of a large slow-moving haemoglobin, with the mobility of Hb F, and a smaller Hb A component (Fig. 1). The identity of the major component as Hb F was confirmed by its resistance to alkali denaturation and its mobility on agar-gel electrophoresis, *p*H 6·2. The alkali-resistant haemoglobin, examined on many occasions by the method of Singer *et al.*[4], ranged between 58 and 69 per cent, while the distribution of Hb F in the erythrocytes[5] resembles that of a new-born infant. Hb A_2 was detected on starch-gel only with a highly sensitive benzidine stain (Fig. 1). Quantitative estimation on diethylaminoethyl (DEAE) cellulose column chromatography[6] gave very low Hb A_2 values, 0·3–0·5 per cent. On starch-gel[7], the patient's non-haemoglobin protein pattern resembled that of the new-born infant (Fig. 2). Specific staining for carbonic anhydrase by Haüsler's modification[8] of Kurata's method[9] disclosed a marked deficiency of carbonic anhydrase activity (Fig. 3). Also with the method of Tashian and Shaw[10] it was demonstrated that both the CA-I type as well as the CA-II type of carbonic anhydrase, identical with respectively *B* and *C* type[11], were deficient (Fig. 4), and the deficiency was also indirectly demonstrated by the nearly complete absence of esterase activity on those spots (Fig. 5). Additional unusual carbonic anhydrase activity was not demonstrated. Quantitative estimation of erythrocytic carbonic anhydrase by the

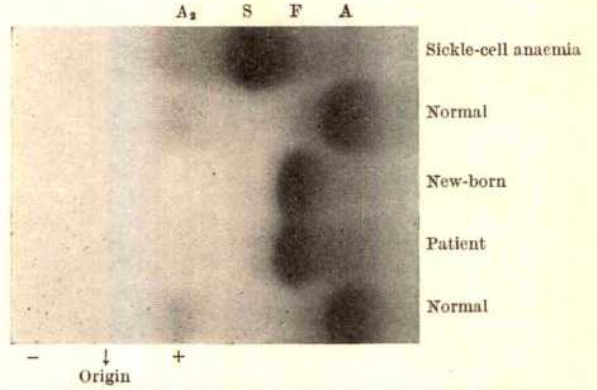

Fig. 1. Starch-gel electrophoresis in *tris*-EDTA-borate buffer *p*H 8·6 and specific benzidine stain, showing patient's haemolysate compared with controls. Note almost absence of Hb A_2 in the patient and the new-born infant

method of Wilbur and Anderson[12] showed pronounced deficiency in activity. Catalase examined by Tudhope's method[13] showed normal activity and mobility.

The patient's parents were dead. His only son and only daughter, two brothers and two maternal uncles had normal amounts of Hb A_2, no increase of Hb F and no clear evidence of red blood cell abnormalities except for one brother who, however, had alcoholic cirrhosis of the liver. No deficiency of erythrocytic carbonic anhydrase was detected in these relatives.

From the foregoing data, it can be concluded that the patient could not be homozygous for beta-thalassaemia or hereditary persistence of Hb F, while the increase of Hb F was too high for the heterozygous state. Hereditary persistence of Hb F associated with beta-thalassaemia is improbable since the children did not have increase of Hb F or Hb A_2. In both hereditary persistence of Hb F associated with alpha-thalassaemia as well as with delta-thalassaemia[14], one would not expect the increase of Hb F to be higher than 50 per cent as in both conditions only one gene leads to depression of the production of beta-chains. In the only reported case of hereditary persistence of Hb F with alpha-thalassaemia[15] the Hb A_2 level was normal, and the Hb F was increased to only 17 per cent. In the recently described cases of hereditary persistence

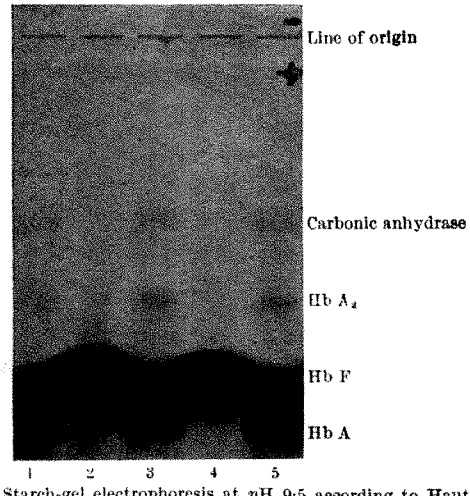

Fig. 2. Starch-gel electrophoresis at *p*H 9·5 according to Haut *et al.* (ref. 7) of patient's haemolysate compared with those of a new-born infant and of normals. 1, 3 and 5, Normals; 2, patient; 4, new-born infant. Note the almost absence of Hb A_2 in patient and the resemblance of the non-haemoglobin protein pattern with that of the new-born infant

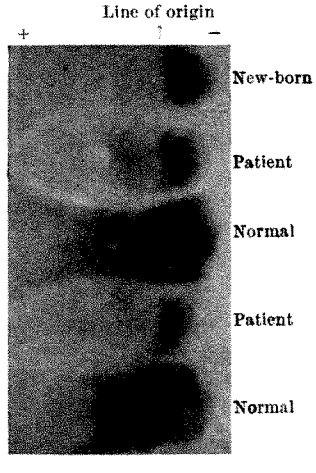

Fig. 3. Paper electrophoresis in veronal buffer *p*H 8·6, followed by specific staining with Haüsler's modification (ref. 8) of Kurata's method (ref. 9). Patient's haemolysate compared with those of a new-born infant and two normal adults. Note marked deficiency of carbonic anhydrase in the patient and new-born infant. Haemoglobin spots had migrated to the left, not seen in the picture

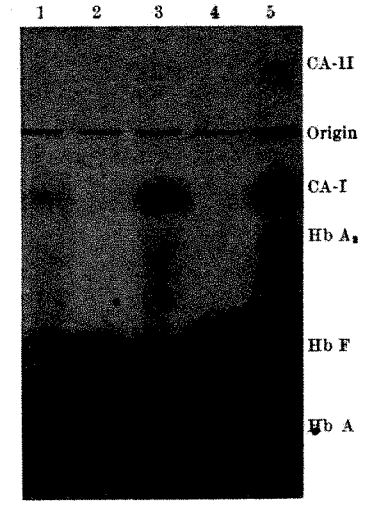

Fig. 4. Starch-gel electrophoresis in borate buffer *p*H 8·77, 0·02 M, (ref. 10). Protein stain with amido black. 1, 3 and 5, Normals; 2, new-born infant; 4, patient. Note marked deficiency of CA-I as well as CA-II type carbonic anhydrase, almost absence of Hb A_2 and increase of Hb F in the haemolysate of the patient and the new-born infant

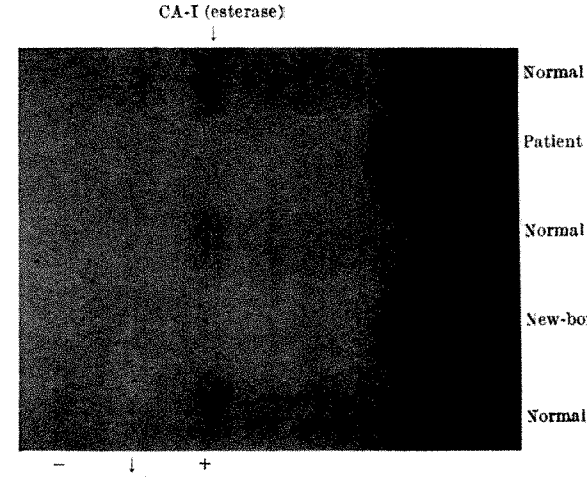

Fig. 5. Starch-gel electrophoresis in borate buffer *p*H 8·7 for esterase activity pattern. Enzyme activity visualized with Blue *RR* salt as dye-coupler and α-naphthyl acetate as substrate

of Hb F in association with delta-thalassaemia[16] the increase of foetal haemoglobin was less than 50 per cent, while the trait delta-thalassaemia was associated with a low Hb A_2 level. Therefore, it seems that our patient's condition does not fit in any of the hitherto known disorders.

In addition, the patient had pronounced deficiency of carbonic anhydrase, an important enzyme in the erythrocytes that catalyses the reaction

$$CO_2 + H_2O \underset{\leftarrow}{\overset{\text{carbonic anhydrase}}{\rightleftharpoons}} H_2CO_3 \rightleftharpoons H^+ + HCO_3^-$$

both ways. It is to be expected that a severe deficiency of carbonic anhydrase would lead to slowing of the reaction and possibly to accumulation of carbon dioxide and to difficulties in taking up oxygen. It appears fortunate that most of the patient's haemoglobin was of the foetal type, just as in a new-born infant, since foetal haemoglobin is a more suitable type under hypoxic conditions because of its high oxygen affinity and its ability to bind oxygen at a higher carbon dioxide pressure. This raises the question of the relationship between the carbonic anhydrase deficiency and the persistence of foetal haemoglobin in our patient. It has been shown that the synthesis of carbonic anhydrase and the hereditary persistence of Hb F are under separate genetic control[1]. In our patient,

the possibility that deficiency of carbonic anhydrase is the primary defect calling for compensatory adjustments in haemoglobin synthesis has to be considered and is suggested by the failure to find an increase of Hb F in the relatives, although at least four of those examined could have inherited the high *F* gene. The substantial carbonic anhydrase deficiency in our patient may represent the homozygous state or the heterozygous dominant trait of a hitherto undescribed abnormality. In the first assumption the trait condition may not be well expressed in this abnormality, thus the lack of convincing evidence in the relatives.

Abnormal young white blood cells in the bone marrow, and occasionally in the peripheral blood, and the hepatosplenomegaly in the patient raised the question of whether or not the patient had leukaemia. However, this would not explain his red blood cell changes and the biochemical findings. On the other hand, these changes might also have been brought about by the functional disturbances implied in the biochemical abnormalities.

A recently described case of deficiency of the *B* (CA-I) type of carbonic anhydrase[17] was not accompanied by deficiency of the *C* (CA-II) type and quantitative analysis of the total activity of carbonic anhydrase was normal. In both parents of that case no abnormality of carbonic anhydrase was demonstrated. A deficiency of carbonic anhydrase with variable increase of Hb F up to 30 per cent and decrease of Hb A_2 was described in Down's syndrome in neonates and young infants[18]. As the triad of high Hb F, low Hb A_2 and carbonic anhydrase deficiency is physiologically found in new-borns, it is not surprising to find it also in young infants having various disturbances. In our patient, however, the change-over from neonatal to an adult type of synthesis should have been well established. He also did not show the Down's syndrome and an investigation carried out by Dr. David Linder from the Childrens Hospital, San Francisco, showed the chromosomes to be normal.

RESISTANCE OF *Plasmodium chabaudi*-INFECTED WHITE MICE TO A FULMINATING AND FATAL STRAIN OF *Plasmodium vinckei*

By PROF. MEIR YOELI, DR. RUTH NUSSENZWEIG, MISS RASMA S. UPMANIS and PROF. HARRY MOST
New York University School of Medicine, Department of Preventive Medicine, 550 First Avenue, New York

IT is well known from studies of therapeutic malaria in general paresis that plasmodial infections of man induced by sporozoites or infected blood, and allowed to run a natural and protracted course, will confer on their hosts a state of protection against re-infection. This resistance, acquired as a result of mobilized and enhanced cellular and humoral defences, is strain specific and is less pronounced against other geographically remote strains. No true protective cross-immunity between different plasmodial species has been observed. The natural resistance encountered among certain human races against malaria infections, such as the resistance of the American Negro against *Plasmodium vivax*, has also been found to be only strain specific in its nature.

It has, therefore, generally been assumed that the state of resistance of populations in highly endemic malaria areas is a result of the total exposure of all individuals to the plasmodial species and strains of the region, and the degree of such resistance, a measure of the intensity and frequency to sporozoite exposure.

The *in vivo* protection afforded by a naturally suppressed malaria infection to its host has been used in the past as one of many criteria for the definition of a true plasmodial species. Thus, the late Prof. Rodhain, when working with two rodent malaria parasites, *P. berghei*[1] and *P. vinckei*[2] isolated from the region of Katanga in the Republic of the Congo (and carried by a common vector—*Anopheles dureni*), was able to show the absence of cross-immunity and protection among the two species[3]. This demonstration provided further clinico-immunological evidence to earlier observed morphological differences and host specificity of the two plasmodia. More recently, Zuckerman[4], when studying the antigenic components of these rodent malaria parasites, was able to demonstrate by methods of immunoelectrophoresis the differences in the mosaic antigenic structure of these two species, though antigens common to both plasmodia were also found.

The recent discovery in the Central African Republic (R.C.A.) of a new rodent plasmodium, *P. chabaudi*[5], has afforded an opportunity to investigate immunological relations and protective mechanisms among the different rodent malaria parasites. The observations which are the basis of the present article describe such a protective action of one plasmodium (*P. chabaudi*) against massive inocula of a fulminant and fatal related species (*P. vinckei*).

P. chabaudi (Landau, 1965) shares most of the morphological characters and patterns of behaviour of the earlier discovered *P. vinckei*. Both species show a very distinct preference for invasion and development in mature, haemoglobin-rich erythrocytes. Their schizonts occupy only part of the infected cell and contain from six to twelve merozoites. The white mouse, the young albino rat and the tree rat (*Thamnomys surdaster*) are susceptible hosts; the adult golden hamster (*Mesocricetus auratus*) is resistant to both. The claim of *P. chabaudi* to represent a true species rests at present in its distinct ecological environment, both in the rodent host (*Thamnomys rutilans*) and in its mosquito vectors, in the different growth and temperature requirements, and morphology of its sporogonic stages in experimental mosquito vectors (*A. stephensi*)[6] and differences in the pre-erythrocytic

schizogony (Garnham *et al.*[7]). A striking difference between *P. chabaudi* and *P. vinckei* may also be observed in the course of blood-induced infections of the two plasmodia in the white mouse. The course of *P. chabaudi* is prolonged and chronic. Parasitaemias progressively rise to reach a first peak at about the eighth day, descending to low levels and passing into latency, with an occasional exacerbation in subsequent months. The inapparent infection may be revealed by subinoculation of blood into a susceptible host. *P. vinckei*, on the other hand, causes in the white mouse a fulminating and invariably fatal infection. Death of the infected animals occurs within 5–7 days after intraperitoneal inoculation of a million parasitized red blood cells (RBC). Parasitaemias are always very high, ranging between 51 and 96 per cent at their peak.

A number of experiments were carried out in order to detect if cross-immunity between *P. chabaudi* and *P. vinckei* existed.

In a preliminary trial, thirty-two white mice (*C.F.I.* strain) were each inoculated with 1 million *P. chabaudi* parasitized erythrocytes (from the eighth blood transfer) and the course of their plasmodial infection followed. On the 43rd day following their inoculation, sixteen mice of this group were challenged, each with ten million *P. vinckei* parasitized red cells. The remaining animals were kept for observation of their chronic latent *P. chabaudi* course. Sixteen normal white mice of comparative age were also given identical inocula of *P. vinckei* and served as controls. Daily blood smears were obtained from all the animals, and the degree of parasitaemia determined by the percentage of infected erythrocytes per ten thousand cells counted. The results of this experiment have clearly shown that whereas all control *P. vinckei* mice succumbed to their fulminant plasmodial infections within 5 or 6 days, no deaths occurred among the latent *P. chabaudi* challenged mice. Parasitaemias in this group were generally low, and animals which showed elevated parasite counts were able afterwards to control and suppress their infection. Fig. 1 summarizes parasitaemias in each of the control and challenged groups of mice, as seen from daily parasite counts.

In a second experiment, twenty-four white mice were challenged with *P. vinckei* after shorter periods of exposure to *P. chabaudi* (3–5 weeks). The results were similar to those obtained in the first group. No deaths were observed among the challenged animals. Experiments since carried out have demonstrated that protection against fatal *P. vinckei* infections in mice previously exposed to *P. chabaudi* appears early. Mice infected with *P. chabaudi* and re-inoculated 7 days later with a million *P. vinckei* parasitized cells survived their challenge infection and were able to lower and even suppress parasitaemia. On the other hand, *P. chabaudi* and *P. vinckei*, inoculated in mice simultaneously, failed to protect their hosts, and the animals succumbed to their concomitant infections within 5–6 days with overwhelming parasitaemias (74·5–86 per cent).

It would seem, therefore, that resistance to the usually fatal inocula of *P. vinckei* develops in white mice within the first week of their active *P. chabaudi* infection. A more

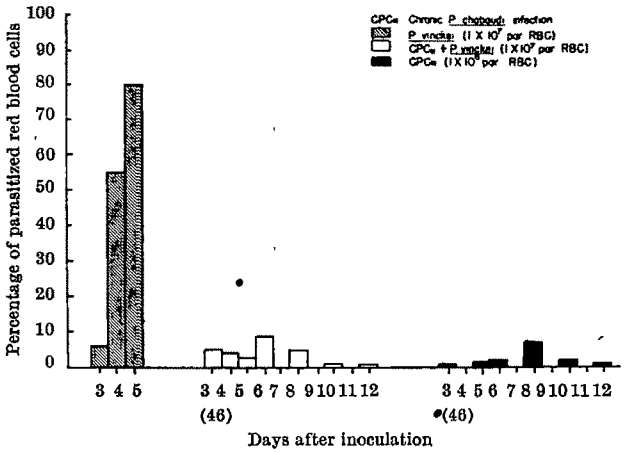

Fig. 1. *P. vinckei* and *P. chabaudi* parasitaemias in white mice, as compared with *P. vinckei* in chronic *P. chabaudi* mice

detailed investigation on this problem—the exact time of appearance of this protection, its duration and evanescence, as well as its manifestations *in vivo* and possibly *in vitro*—is at present being carried out.

Our experiments have further shown that the shielding action of *P. chabaudi* against fulminant and fatal *P. vinckei* infections is powerful enough to protect their hosts even against very massive inocula of 100 million and one billion (10^9) parasitized erythrocytes. Table 1 summarizes the results of a comparative study in which inocula of varying strength of *P. vinckei*, *P. chabaudi* and *P. berghei* were administered to groups of white mice, 43 days earlier exposed to *P. chabaudi*. It should be noted that at the time of their challenge inocula most mice had very light or suppressed *P. chabaudi* infections.

It will be seen from the results of these experiments (Table 1) that when a million *P. chabaudi* infected red cells are given to normal white mice (*C.F.I.* strain), a chronic and protracted infection ensues. Parasitaemias after early elevations fluctuate and the infection in the majority of the animals is suppressed to submicroscopic levels. However, in some animals maximum parasite densities may be encountered as late as the 70th day in their infection. A mortality of about 20 per cent among *P. chabaudi* mice has been observed. Death appears late in the course of the infection. Enhanced virulence has not at present been found to occur after eighteen successive blood transfers.

Higher inocula in normal white mice alter the course of the infection. Maximal parasitaemias are comparatively higher and more pronounced and the parasite peaks appear earlier in the course of the infection. Death in these animals is not the end result of a prolonged disease, but appears early in the 6th or 7th day in the course of their plasmodial infection.

In the groups of mice initially exposed to a million *P. chabaudi* and challenged 43 days later with 10 million or 100 million parasitized cells from stabilates of the homologous strain, all animals recovered. Parasitaemias were

lower than in the controls and were readily suppressed. 82 per cent of the mice challenged with massive (100 million or 1 billion (10^9) *P. vinckei* infected cells) survived and recovered.

Even in the fatally terminating infections of this group, the course of the disease was twice as long as in the *P. vinckei* controls (12·7 days against 5·4 days).

The course of *P. berghei* in the *P. chabaudi* latent mice was greatly different. The infection was invariably fatal, and though parasitaemias did not greatly differ in this group from that of the *P. berghei* controls, death, as the outcome of a combined plasmodial infection, appeared earlier in the *P. chabaudi* latent animals challenged with *P. berghei*.

The protective phenomenon described herewith from rodent malaria is of considerable interest. Though immune-reactions and *in vivo* protection have long been known to occur in some protozoal infections, and a state of pre-immunity to homologous plasmodial strains observed, it was generally assumed that such protective phenomena necessitated a prolonged period of immuno-alertness of the host and prolonged antigenic stimulation. The early appearance of a strong resistance in mice inoculated with *P. chabaudi* to fatal inocula of *P. vinckei*, a related yet geographically distinct species, points to the existence of other immuno-mechanisms, early awakened and powerfully triggered. The exact nature of this mechanism is at present unknown. Its general implications in malaria immunity and its exact significance in the relationship of *P. vinckei* to *P. chabaudi* are at present being investigated.

This work was conducted under the sponsorship of the Commission on Malaria, Armed Forces Epidemiological Board, and supported in part by the Office of the Surgeon General, U.S. Department of the Army, and by the National Institute of Allergy and Infectious Diseases, U.S. National Institutes of Health.

We thank Dr. Irène Landau, Laboratoire de Zoologie (Vers), Museum Nationale d'Histoire Naturelle, Paris, for the strain of *Plasmodium chabaudi*, and Prof. I. H. Vincke, Institut Medecine Tropicale, Prince Leopold, Anvers, for the strain of *Plasmodium vinckei*.

SPONTANEOUS MOVEMENTS IN THE EMBRYO OF *Eleutherodactylus martinicensis*

By Dr ARTHUR HUGHES
Department of Zoology, University of Bristol

Larval development requires that a functional system of locomotion should be present from the beginning of free life, a necessity from which the embryo, provided with nourishment and sheltered from the outside world, is relieved. This consideration profoundly affects the development of neuromuscular co-ordination of bodily movement in these two sets of circumstances. Among those vertebrates in which part of the developmental period is spent in a larval form, the nervous and muscular systems are then made up of comparatively few elements arranged in relatively simple relationships. In the neural tube of larval Amphibia the primary sensory and motor systems are largely separate from the centres which will innervate the limbs at a later period of development.

The ontogeny of movement was first systematically investigated by G. E. Coghill in the embryo and larva of *Amblystoma punctatum*. On the basis of a long series of behavioural and neuroembryological experiments on this species, he stated a general thesis that from an early background of a total pattern of movement, individual elements gradually emerged and became distinct, and were ultimately independent of general activity[1]. At the present time this conception is considered of dubious relevance to the development of vertebrates higher in the series, the ontogeny of which is either embryonic or foetal[2]. The alternative view has been formulated that the behaviour pattern of the foetal mammal is built up by the summation of separate individual reflexes[3].

Recently, a series of investigations by Hamburger *et al.*[4–6] has shown that the chick embryo spends much of its time in spontaneous activity of its members, each movement of which generally lacks any co-ordination with that of any other. At the same time, locally co-ordinated reflex actions can result from external stimuli. The developing chick has thus two quite separate patterns of behaviour—a collection of reflexes which in normal development are never exhibited, and on the other

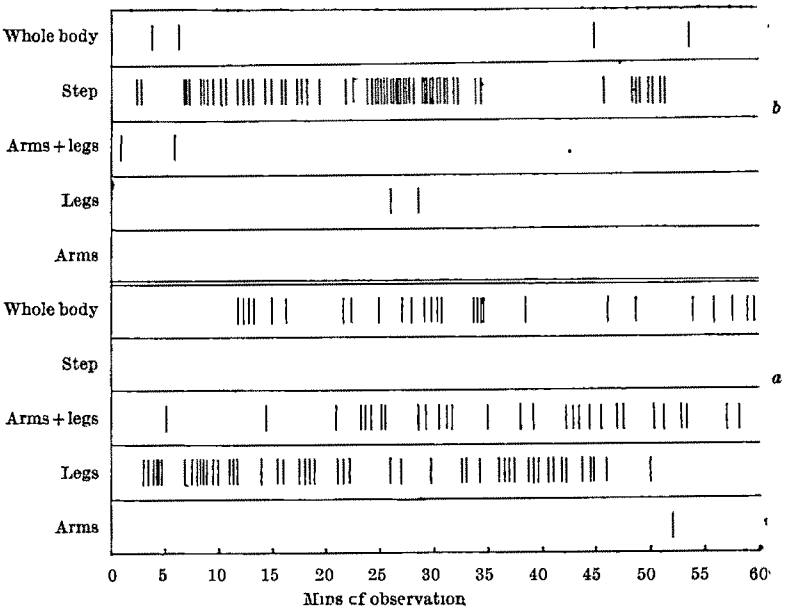

Fig. 1 Analysis of spontaneous movements occurring during 1 h in an embryo of *Eleutherodactylus*. (*a*) At 9 days, at the stage of reflex leg withdrawal, (*b*) 6 days later at juvenile stage, with no tail

hand its repertoire of spontaneous random movements of head, trunk and limbs.

How widely and on what scale does spontaneous behaviour exist in other embryos? Very little is known of such movements in mammals except that they exist[3]. Special interest attaches to the question whether two separate modes of developmental behaviour occur in those Amphibia which have an embryonic development, in view of the close relationships which members of the group with this type of ontogeny bear to the great majority the development of which is mainly larval.

In the bufonid genus *Eleutherodactylus*, which is widely distributed in the Caribbean and on the adjacent mainland, development is wholly embryonic[7]. Larval features in pharynx and aortic arches of other amphibia are suppressed, and the tail has acquired a new respiratory function within the egg envelope. In those species which are found in tropical habitats, development is very rapid. The eggs are laid in damp places but will continue to develop when freed from their envelopes and are immersed in water or saline. They are then completely accessible to observation and to experiment. So far, they have been used in endocrinological[8] and neuro-embryological researches[9–11].

The normal reflex pattern of behaviour in *E. martinicensis* has recently been described[12]. In this species, development at 20° to 30° C occupies 13–14 days from the laying of the eggs until the hatching of the fully formed juvenile. The first movements of the limbs occur at 7·5 days, during period of flexion of the trunk. At 8·5 days a withdrawal reflex of the hind limb independent of trunk movement can be seen on light stimulation. At 10 days, flexion of the hind limb is followed by extension, which gradually becomes more vigorous, and is then known as a "kick". In the following days, the leg becomes capable an increasing series of repeated kicks, which build up into bilateral swimming movements, as the arms become co-ordinated therewith. At first, incomplete swimming strokes are seen, which gradually extend in scope until, at the hatching stage, the animal can swim continuously for several seconds. Thus the reflex behaviour of *Eleutherodactylus* builds up into bilateral swimming.

Recently, the spontaneous behaviour of the embryo has been investigated in the absence of external stimuli. Observations were made on embryos in groups of two continuously over periods of 1 h, and the time of each movement of the embryo was noted under various headings. The data presented here refer mainly to two embryos which were followed over a period of 8 days from the 8·5-day stage when the legs retract on touching, to the second day of juvenile life with no vestige of the tail remaining. Movements of the limbs which were recorded were of the arms alone, of the legs alone, and of arms and legs together, diagonal movements of which were separately scored. In addition, occasions when the animal jumped forwards, or turned round, were noted. Two sets of records are given in Fig. 1*a* and *b*, while in Table 1 the numerical data are summarized, and are also set out graphically in Fig. 2.

The number of individual movements recorded during 1 h ranges from 15 to 107. They are less frequent during the early phase of atrophy of the tail. They are mostly of brief duration; no attempt was made to measure the time occupied by each movement, but it was always less than 1 sec. If we assume an average duration of 0·5 sec.

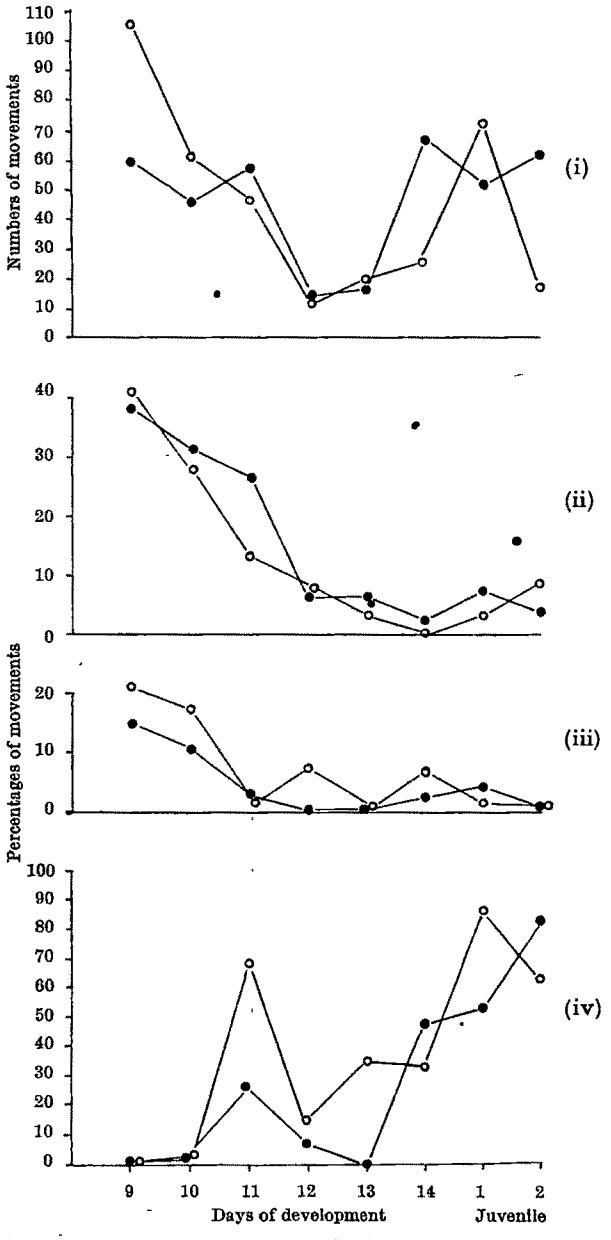

Fig. 2. Spontaneous movements occurring during periods of 1 h in two embryos of *Eleutherodactylus* at the stage indicated. Observations on 8 successive days. (i) Total number of movements (as in Table 1). (ii) Percentages of leg movements alone. (iii) Percentages of trunk movements. (iv) Percentages of steps, that is, diagonal arm and leg movements

then the proportion of time that the animal spent in movement during the periods of observation is generally less than 1 per cent, a very small proportion compared with the chick embryo, which may be active for 80 per cent of the time. In *Eleutherodactylus* embryos the number of spontaneous movements is at a minimum a day before the resorption of the tail begins.

A second point of difference from the chick is that although single limbs may show spontaneous movement,

Table 1. ANALYSIS OF SPONTANEOUS MOVEMENTS IN TWO EMBRYOS OF *Eleutherodactylus martinicensis*

Days of development	9	10	11	12	13	14	Juvenile +1	Juvenile +2
Stage	Egg tooth	Early xanthophores		Tail dwindles 1·5–2·0 mm	1·2–1·5 mm	0·6–1·0 mm	Tail gone Air breathing	
Reflex behaviour	Leg retraction	Leg extension	Repeated kick	Swims				
Total movements	61, 107	47, 61	49, 59	13, 15	17, 20	27, 68	51, 73	18, 83
Leg movements alone	24, 44	15, 17	7, 16	1, 1	1, 1	0, 2	2, 3	1, 2
Movements involving trunk	9, 24	5, 11	1, 2	0, 1	0, 0	2, 2	2, 1	0, 0
Stepping movements	0, 0	2, 3	15, 34	1, 2	0, 7	9, 33	27, 64	12, 52

the proportion of total movements of this kind falls to a very low level by the end of development. Most movements involve both arms and legs, and must therefore originate in impulses within neurones elsewhere than in the motor cells of the ventral horns. The extent to which trunk movements are involved decreases with time in both spontaneous and in reflex behaviour.

Simultaneous arm and leg movement towards the end of development is largely diagonal in pattern, and clearly foreshadows ambulation. In the late embryo, these conjoint movements gradually build up into complete walking steps. There is then a strong tendency for repetition of step movements, to the gradual exclusion of other types of spontaneous behaviour. Thus, whereas reflex behaviour in *Eleutherodactylus* builds up into bilateral swimming, spontaneous behaviour builds up equally gradually into diagonal walking. Accordingly, Hamburger's dictum that the two modes of activity are entirely separate[13] is further exemplified.

At the "repeated kick" stage of reflex behaviour, the embryo is spontaneously attempting ambulatory movement. There is no control over balance in these first faltering steps; the embryo often falls forwards, or on its side. Each movement is incomplete and the embryo may hold bizarre poses with an outstretched arm or leg until the action is resumed many seconds later. It thus seems that proprioception does not enter into these early ambulatory movements, although its presence has been postulated to explain why leg extension follows flexion in the contemporary pattern of reflex behaviour[11].

The separate nature of the two types of embryonic behaviour in *Eleutherodactylus* was further illustrated in some experiments in which embryos had been subjected to some 12 h of anaesthesia induced by a 1/10,000 w/v solution of *MS* 222 (ref. 14) and were recovering on re-immersion in saline. Control embryos of the same age by this time were showing the kick reflex, but this did not yet appear in the anaesthetized embryos, even after full recovery. Before this point, however, spontaneous movements appeared after 5–10 min in saline, and were then maintained at a level greater than normal for embryos of this age. No reflex responses were obtained by touching the legs until 35–50 min from the beginning of the recovery period. Thus, for about 30 min while the reflex pathways were still anaesthetized, spontaneous behaviour was the only mode of activity of the embryo.

The existence of two modes of behaviour may thus be regarded as a feature of embryonic life in which *Eleutherodactylus* resembles the chick, despite the differences in their respective patterns of spontaneous movement. Thus we can already say that this type of movement is not found exclusively among amniote vertebrates, the development of which *Eleutherodactylus* again resembles in that the limb buds appear relatively early in development[9], and independently of any influence of thyroxin[8]. The ontogeny of *Eleutherodactylus* is in this respect unlike that of larval amphibia. It may well be that larval development among tetrapods is as much a specialization as a primitive feature.

CLASSIFICATION, PROBABILITY AND UTILITY

By Dr. D. W. GOODALL

C.S.I.R.O. Division of Mathematical Statistics, Western Australian Regional Laboratory, Nedlands, Western Australia

In recent publications, Williams *et al.*[1,2] discussed the logical basis of classification, with special reference to numerical methods and to the role of probability in the process. Such a discussion was long overdue, and many of the points they make will win general assent.

Williams and Lance[2] point out that the individuals classified on one hand, and the attributes used in their classification on the other, may each be a finite set, completely known, or may be samples from an infinite population. The same, they say, may apply to the uses to which the classification is to be put. Where the uses constitute the only infinite set, they argue, probability has no meaning and the classification must be based on profitability. Williams and Lance do not attempt to define "profitability", but some discussion of this will be attempted; the term "utility" seems, however, preferable.

Utility in single-purpose classification. A particular use for a classification may often be expressed in terms of another classification. A classification of microfossils might, for example, be directed to identification of the geological strata from which they were derived. Their stratigraphical origins, when known, then provide a use-classification. In such cases, the utility of a proposed classification may be assessed by comparing it with this use-classification which, *ex hypothesi*, is optimal. A loss function is defined for each type of misclassification, and the classes of the proposed classification are mapped on to those of the use-classification in such a way as to minimize this loss function. The different minimal values for the loss function then provide a basis for comparing the utility of different proposed classifications.

In other cases, the use of the classification may be expressed in terms of prediction of a continuous variable. The utility of different classifications can then be compared in terms of the proportion of the total variability of the predicted variable contained in the inter-class comparisons.

Utility in multi-purpose classifications. Where the classification is to serve more than one use, the different loss functions for mis-classifications must be combined in order to compare the utility of two alternative systems. This is possible only where the loss functions can be expressed in the same terms, and even so they require arbitrary weighting. Where the loss functions are not even commensurable, comparison of different classifications on the strict basis of utility becomes impossible.

In all cases where the classification is to serve a finite set of uses, Williams and Lance term it "extrinsic", and expressly exclude it from consideration. Their remarks on profitability (= utility) therefore are strictly related to the case where the uses are infinite. But here the considerations of the preceding paragraph apply *a fortiori*, so that any treatment in terms of utility *sensu stricto* is out of the question. An artificial substitute may, however, be proposed. Any particular use will presumably be best served by separating the individuals into classes according to some function of their observed attributes. For different

uses, different functions may be required, and different weights given to the various attributes. It is accordingly suggested that the utility of a general-purpose classification be defined as its ability to predict the differing values of an attribute selected at random (compare with Williams and Lance's "informativeness").

With this arbitrary definition of utility for a general-purpose classification, probability and utility clearly come together. The estimate of utility will depend on the chance selection of an attribute for prediction. Estimates in respect of different attributes will form a frequency distribution, and permit a significance test of differences in utility between classifications.

It should be noted that this approach does not require either individuals or attributes to be a sample from an infinite population. It is valid even if the attributes are limited in number and completely known, and not only where those observed are regarded as a sub-set of an infinite set of observable attributes—the case envisaged by Williams and Lance when they write of the behaviour of further attributes as a test of profitability.

Measurement of the utility of a classification. To apply the general principle above requires that "ability to predict" the values of an attribute should be defined exactly. A solution to this problem will be outlined here.

Considering first the prediction of values of a quantitative (metric) attribute, if two classification procedures each divide the same set of individuals into the same number of classes, that procedure will have the greater predictive ability which gives the larger inter-class and the smaller intra-class variance—that is, which has the larger intra-class correlation. Where two classification procedures distinguish different numbers of classes, the appropriate basis for comparison seems to be the probability of the calculated intra-class correlation on the null hypothesis that the inter- and intra-class variances are equal.

For a qualitative attribute the information content of the inter-class comparisons may take the place of inter-class variance. Where the numbers of classes differ, an approach based on probability may again be suggested. For each number of classes, all possible partitions of the observed values of the attribute into that number of sets may be considered, and the proportion of such partitions with inter-class information content equal to, or greater than, that of the proposed classification may be computed. These estimates of probability, on the null hypothesis of random partition, may then be compared and the classification giving the less probable value of inter-class information selected.

We may now revert to the foregoing proposal that the utility of a general-purpose classification should be defined as its ability to predict the values of a random attribute. For any particular attribute we have suggested that prediction ability be regarded as a strictly decreasing function of the probability of the inter-class variance (information) on the hypothesis of random partition. The negative logarithm of the probability seems an appropriate function to choose. Accordingly, one may propose as a measure of utility:

$$U = E\ \{ - \ln P_i \}$$

where E stands for expectation, and P_i is the probability that a random partition of the values of the ith attribute into the same number of classes will concentrate as much or more information (variance) into the inter-class comparisons as in the classification considered. This expectation will be:

$$-\frac{1}{n} \sum_{i=1}^{n} \ln P_i$$

where the n attributes observed are considered as a complete set, and will be estimated by the same expression where they are a sample of a larger set.

It may be noted that this proposal can be immediately linked with classification for a specific purpose, for here:

$$U = -\ln P$$

where P is the probability, corresponding with P_i above, in respect of the particular attribute the prediction of which is desired.

The classification of samples. The foregoing remarks, and the concept of utility developed, apply irrespective of whether the set classified is to be regarded as complete, or as a sample from a larger population. It is to the latter case only that Williams and Lance regard probabilistic considerations as applying.

Sampling theory has never been satisfactorily applied to classification procedures. That the classifications derived by applying a specified procedure to replicate samples of individuals will themselves be subject to the vagaries of sampling is clear enough. But a classification is not itself a member of that class of objects to which probability concepts apply. Probability statements are made about events—real or hypothetical—and express a relationship between a defined sub-set of events and a defined set including it. A classification is an arrangement of individuals into classes, and as such has no probability whether or not the individuals form a sample from a larger set. One may ascribe a probability to a particular feature of the classification resulting when a specific procedure is applied to a sample of individuals from a specified population, and this may be what Williams and Lance had in mind. One may, for example, speak of the probability that this procedure will distinguish classes at all, or that individuals in a particular sub-set will all be allotted to the same class. But to ascribe a probability to the whole results of a classification procedure seems likely to be meaningless.

In order to apply probability concepts to classifications of repeated samples, it is accordingly necessary for attention to be fixed on particular features of the classification, rather than to consider it as a whole. It would be possible, for example, to determine a frequency distribution for the number of classes to be distinguished. The most suitable single expression of the value of a classification seems, however, to be its utility, as defined above. In repeated samples, this too will have a frequency distribution, and the frequency distributions of utility for classifications by two differing procedures could appropriately be used to compare their value.

It should be noted, however, that though this interpretation of the sampling properties of a classification has been described in connexion with an actual sampling of individuals, it is also meaningful where the observed set of individuals constitute the whole population. In this event, the observations can be treated, under a null hypothesis, as a sample from a hypothetical population in which the observed values of each attribute are distributed at random and independently between different classes. The single observed value of utility, not itself subject to sampling error, can then be compared with the expected distribution of utility in samples from the hypothetical population.

Willams and Lance suggest, as a possible strategy where probabilistic considerations apply, the independent classification of two separate samples followed by a comparison of the results. But even comparisons between classifications must usually be confined to extracted statistics (such as their utility) rather than covering all features. The first requirement for a general comparison between classifications of two samples would probably be that the classes of one should be mapped on to those of the other; in the general case this may be fraught with great difficulties. Consequently, the comparisons suggested by Williams and Lance would be unlikely to go beyond the rather subjective level they envisage.

LETTERS TO THE EDITOR

ASTROPHYSICS

Lithium in the Peculiar Star *HD* 101065

In a recent article[1] Przybylski presented the results of a preliminary coarse analysis of element abundances in the atmosphere of the peculiar star *HD* 101065. This star, the spectrum of which consists almost entirely of rare earth lines, is of considerable interest as it apparently represents a very advanced stage of nuclear evolution. In order to decide where *HD* 101065 fits into the scheme of stellar evolution at present accepted, a quantitative knowledge of the composition of its atmosphere is necessary. Przybylski's work provides a valuable first step in this direction.

I will report here some observations made at the Radcliffe Observatory, Pretoria, in 1965, that provide additional information on the composition of *HD* 101065. A number of coude spectra were obtained with the 74-in. reflector giving complete coverage of the spectrum from 3370 Å to 6867 Å. In the photographic region the dispersion is 6 8 Å/mm and in the visual 13·6 Å/mm. The latter plate will be discussed here. The exposure was 6 h, and the spectrum was widened to 0·30 mm. The density is suitable for microphotometric measurements over most of the range 5500–6880 Å, and is particularly good in the region of Hα. Wave-length measurements on this plate confirm that the majority of the observed spectrum lines are due to the once ionized rare earth elements. In the region 5500–6880 Å nearly every rare earth ion line tabulated by Meggers *et al.*[2] appears in *HD* 101065 (accounting for nearly all the strong stellar lines) and with relative intensities roughly similar to the laboratory observations.

The main point to be made in this communication is confirmation of Przybylski's suggestion of the occurrence of the 6707·8 LiI line in the spectrum of *HD* 101065. Przybylski pointed out that the SmII line at 6707·45 Å should occur in *HD* 101065 and was unable to estimate whether the line at 6708 Å in the star was due to LiI or this SmII line.

Fig. 1 is a microphotometer tracing of the region 6685–6720 Å in *HD* 101065. A moderately wide slit was used in order to smooth out grain noise; the measurements to be described later were carried out with higher resolution. Line identifications originate from the tables provided by Meggers *et al.*[2] and their observed (laboratory) intensities appear in brackets. Fig. 2 shows the spectral region near Hα and is on the same scale as Fig. 1.

From the identified lines of SmII in Figs. 1 and 2, it can be seen that the 6707·45 Å SmII line, with laboratory intensity 3·0, cannot account for more than a minor part of the strong feature at 6707·8 Å. As there are no other strong rare earth lines at this wave-length we conclude that LiI is the main contributor.

With the aid of an intensity calibration of the photographic plate the equivalent width of the LiI line (partly dotted in Fig. 1) was found to be 340 mÅ. Following Przybylski's assumption that the atmosphere of *HD* 101065 is physically similar to that of the Sun, and allowing for the increased turbulence[1] in *HD* 101065 and the fact that LiI atoms would have a higher turbulent velocity than rare earth atoms, we deduce a lithium abundance, relative to the Sun, of $\log (N^*(\mathrm{Li})/N^{\odot}(\mathrm{Li})) \sim 2{\cdot}4$ (a correction for line saturation has been made assuming the shape of the curve of growth to be similar to that of the Sun, and we adopt $\log W^{\odot}(\mathrm{Li}) = -6{\cdot}15$).

Accurate measurements of the wave-length of the Li 6708 line can indicate the $^6Li/^7Li$ isotopic abundance ratio in a stellar atmosphere[3]. The extreme positions are 6707·81 Å for pure lithium-7 and 6707·97 Å for pure lithium-6. With the interference from the SmII 6707·45 Å and TbII 6706·79 Å lines (Fig. 1), it is not possible to give a very precise value for the wave-length in *HD* 101065. However, my measurements, with an attempt to allow for interference, give 6707·85 Å for the position of the LiI line, suggesting that at least some of the lithium in *HD* 101065 is in the form of lithium-6.

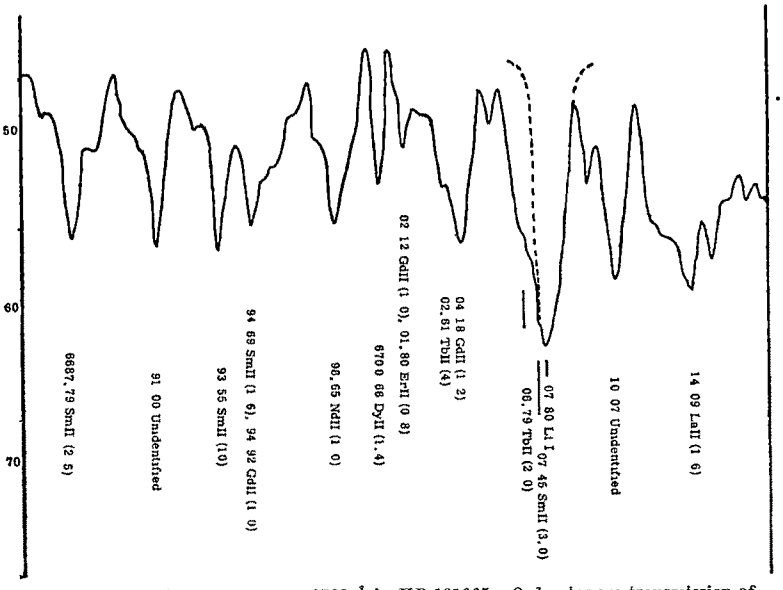

Fig. 1 The spectrum region near 6708 Å in *HD* 101065. Ordinates are transmission of plate

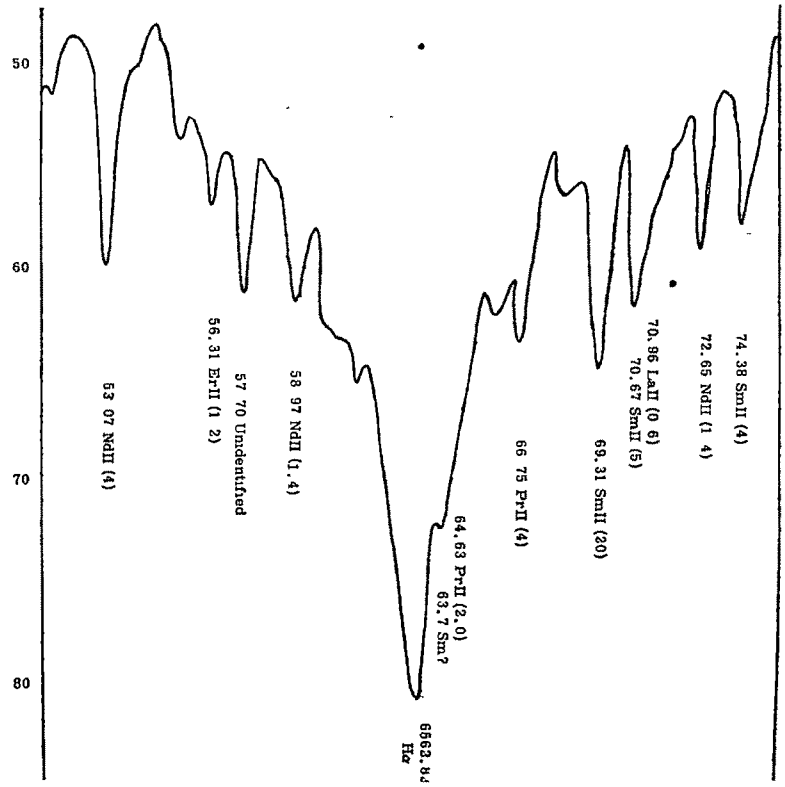

Fig. 2. The spectrum region near Hα in *HD* 101065

From a study of the photographic region, Przybylski was unable to find evidence for the occurrence of lutetium and ytterbium in *HD* 101065. The plate studied here shows the LuII lines at 5476·69, 5983·9, 6221·87 and 6463·12 Å to be present in considerable strength, so lutetium probably has an abundance similar to that of the other rare earth elements. No ytterbium lines can be identified with any conviction. The resonance line at 3694·19 Å should attain great strength if the abundance of ytterbium were similar to that of the other rare earths, but a feature observed near this wave-length is probably attributable entirely to SmII 3694·30 and GdII 3694·03.

The peculiar composition of the atmosphere of *HD* 101065 indicates that high-energy nuclear reactions (in particular the *r*-process of neutron capture) have occurred in the interior of the star and the products mixed to the surface. During such a process all lithium would be destroyed. The lithium observed at present is therefore likely to have been produced from a spallation process on the surface of the star; the probable presence of some lithium-6 is in agreement with this conclusion. Furthermore, if the highly turbulent atmosphere (Przybylski finds a turbulent velocity of 5 km/sec) indicates that the outer parts of the atmosphere are convective, lithium may be transported into the interior and destroyed, so that the observed abundance must represent an equilibrium value. These arguments suggest that *HD* 101065 has a strong magnetic field, by means of which the spallation process is energized. A search for other spallation products (for example, beryllium) and a magnetic field in *HD* 101065 should be undertaken when very large telescopes become available in the southern hemisphere.

Abundance of Boron in the Sun

IN a recent paper, Waddell and Slaughter[1] suggested that the composite feature at 8668·43 Å in the solar spectrum includes a high excitation line of B I. This line is one of a number first reported in the laboratory spectrum of B I by Gunnvald and Minnhagen[2] (Table 1). From the observed central depth of 0·015, a boron: hydrogen ratio of $4{\cdot}0 \times 10^{-7}$ was deduced. The terrestrial ratio[3] is $7{\cdot}6 \times 10^{-10}$, while Russell's[4] photospheric upper limit is $1{\cdot}1 \times 10^{-7}$. This figure was later reduced by Babcock[5] to $2{\cdot}8 \times 10^{-8}$.

Lines from the other multiplets listed in Table 1 should have easily measurable central depths if Waddell's identification is correct. In particular, the lines at 11,660 Å, with a lower excitation potential of 4·96 eV and a total *gf* of 2·14, should be strongly present. A photoelectric record of the solar spectrum in this region taken at the Jungfraujoch[6], with wave-lengths and identifications from Babcock and Moore[7], is shown in Fig. 1. The stronger line at 11,660·05 Å is not well placed. The weaker line, however, falls in an apparently clear region. At 11,662·47 Å the trace shows no feature with a central depth greater than 0·01.

The other multiplets are not so useful, as they have the same lower level as the ^2P- ^2D multiplet. Moreover, the published traces[8] of 15,000–17,000 Å are rather noisy. For the most favourable case, 16,244·66 Å, any feature with a central depth of more than 0·02–0·03 can be excluded.

We have calculated the central depth of B I lines for various values of the abundance using the average column

Table 1

Wave-length (Å)	Transition		*gf* (Coulomb approx.)	*E.P.* (eV)
16,244·66	$2s^2 3p^2 P_{3/2}$–	$2s^2 3d^2 D_{5/2}$	5 462	6·03
16,240 32	$^2P_{1/2}$–	$^2D_{3/2}$		
15,629·01	$3p^2 P_{3/2}$–	$4s^2 S_{1/2}$	1 129	6·03
15,624·66	$^2P_{1/2}$–	$^2S_{1/2}$		
11,662·47	$3s^2 S_{1/2}$–	$3p^2 P_{1/2}$	2·141	4·96
11,660 05	$^2S_{1/2}$–	$^2P_{3/2}$		
8668 570	$3p^2 P_{3/2}$–	$5s^2 S_{1/2}$	0 110	6·03
8667·223	$^2P_{1/2}$–	$^2S_{1/2}$		

of the Utrecht reference photosphere. At the level of formation of a high-excitation B I line ($\tau_{5000}=0{\cdot}1$, $T=5100°$ K, $\xi=1{\cdot}6$ km/sec) the half width, assumed to be wholly Doppler, is 0·207 Å. Waddell's abundance would produce features with central depths of about 0·30 (11,660 Å) and 0·18 (16,244 Å). From the observations at 11,660 Å an upper limit of $4{\cdot}0\times10^{-9}$ can be set with considerable certainty. Weak-line calculations set a limit of $2{\cdot}1\times10^{-9}$ for an equivalent width corresponding to a boron line of central depth 0·01.

A smaller, though less certain, value for this upper limit can be obtained from far ultra-violet observations[9]. Lines of Be I, with a lower excitation potential of 2·71 eV, have been identified at 2495 Å. In laboratory spectra, Clearman[10] has reported two ground state lines of boron at 2496·72 Å and 2496·77 Å. The Coulomb approximation gf values for the two multiplets are 1·42 (Be I) and 0·12 (B I). The product $10^{-\chi}\times gf$ is then $2{\cdot}8\times10^{-3}$ for Be I and $8{\cdot}3\times10^{-2}$ for B I. Allowing for the fact that boron is about half ionized and that the B I lines would be partially masked by other features, it seems very unlikely that boron can be more abundant than beryllium. The Goldberg, Müller and Aller abundance[11] for this latter element is $2{\cdot}3\times10^{-10}$, although the far ultra-violet spectra indicate that this may be too high a value (Kacalov *et al.*[12]). Tousey[13] reports no certain identification of B I and B II lines.

Babcock[5] has reported lines of the Q and R branches of the $A^1\Pi$–$X^1\Sigma$ (0,0) band of BH in sunspots, but has not given any equivalent widths. Using the Zwaan[14] sunspot model, the boron abundance would be given by:

$$\frac{N_B}{N_H}=2\times10^{-8}\,\frac{1}{f_{00}}\cdot\frac{W_J}{S_J}$$

where W_J is the equivalent width, S_J the line strength and f_{00} the band oscillator strength. For the Q branch, lines near the band head will coalesce. The total line strength for the observed head is about 65. Assuming that Babcock detected a feature with $W_J=5$ mÅ:

$$\frac{N_B}{N_H}=1{\cdot}5\times10^{-7}\ (f_{00}=0{\cdot}01)\ \text{or}\ 1{\cdot}5\times10^{-9}\ (f_{00}=1{\cdot}0)$$

Compilations of band oscillator strengths indicate that f_{00} is unlikely to exceed 0·01 by a significant amount. This would yield an abundance near that of Waddell and Slaughter, in disagreement with our upper limit from the B I infra-red lines. Repetition of Babcock's observations is therefore highly desirable.

Waddell's identification of the line at 8668·42 Å as arising from S I seems sound. One other line from the same multiplet is almost certainly present at 8633·18 Å. The strengths of these lines are in the ratio 2 : 1 in LS coupling. Their measured equivalent widths[6] are 8·7 mÅ (8668 Å) and 4·6 mÅ (8633 Å). The calculated central depth for the 8668 Å line is 0·08, which is in fair agreement with observation. The calculated oscillator strength is subject to some uncertainty as the multiplet belongs to the displaced series in S I.

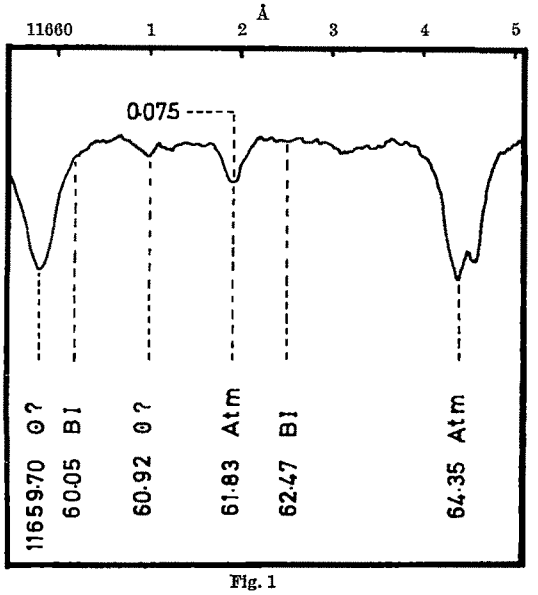

Fig. 1

Davis and Phillips[15] list two CN lines in this region: 8668·567 Å ((3,1) band) and 8668·555 ((5,3) band). Their calculated equivalent widths[16] are 1·5 mÅ and 0·35 mÅ, respectively. The former may in fact be the line Waddell identified as B I λ8668·570 Å. The wave-length and intensity agreement is good. If the line is formed in the region of the temperature minimum ($\tau_{5000}=0{\cdot}01$, $T=4500°$ K, $\xi=2{\cdot}6$ km/sec) its half width would be 0·127 Å. The fact that Babcock and Moore, by not giving any spot intensity, imply that the feature E–F disappears over a sunspot is not a fatal objection to this identification. The S I line would certainly disappear, as it has a lower excitation potential of 8·42 eV. In the 8660 Å region, Rowland intensity-3 corresponds to equivalent widths of 3–4 mÅ. As no weaker lines are listed by Babcock and Moore[7] the E–F feature could still disappear despite considerable enhancement of the CN line. Against this argument must be set Babcock's observation[5] that the number of CN molecules "above one sq. cm of the photosphere" is enhanced by a factor 3 (violet CN)–10 (red CN) over a sunspot.

We conclude that the upper limit to the boron abundance in the Sun can be set about 4×10^{-9}; however, at present there are strong indications that it may be an order of magnitude smaller. Fresh observations of the 11,660 Å region are to be undertaken at Oxford in an effort to obtain more precise values.

Spectra of Nine Discrete Radio Sources in the 20–40 Mc/s Range

During October–November 1964 and April 1965, measurements were made with the 1,000-ft. radio telescope of the Arecibo Ionospheric Observatory[1] for the purpose of determining the spectra in the 20–40 Mc/s range of some of the stronger radio sources having declinations between $-1{\cdot}5°$ and $+38{\cdot}5°$. It should be of interest to compare these measurements, in which a filled aperture pencil beam was used, with other recent measurements[2–4] made below 40 Mc/s using a Mill's cross (T shaped) or spaced interferometric arrays.

With the 1,000-ft. spherical reflector illuminated by a log-periodic feed, the antenna temperature contributions of the various radio sources were measured at 22·30, 26·70, 33·45, and 38·75 Mc/s using four Ryle-Vonberg type radiometers. The antenna has a half-power beamwidth varying between about 2·0° at 38·75 Mc/s and 3·2° at 22·30 Mc/s. A number of runs (some drifts, but mainly driven scans in right ascension and declination) were taken for each source to help separate the source from the background and to lessen errors in measurement which could be statistically averaged out. The use of a fully steerable pencil beam enabled us, in general, to make several measurements per source on the many sources investigated during each night's observational period.

Since the Arecibo Ionospheric Observatory radio telescope consists of a fixed reflector with moving feed, the effective area varies as a function of the zenith angle. Rather than try to derive effective area theoretically, we tracked and measured the antenna temperature contribution of our calibration source Taurus *A* from zenith angles of 3 6° (its nearest approach) to 20° (the telescope limit). For our calculations a flux density of $2{,}300 \times 10^{-26}$ W m^{-2} (c/s)$^{-1}$ at 38 Mc/s with a constant spectral index of 0·27 was assumed[5] and effective area curves were plotted for the four operating frequencies. For small zenith angles, effective areas of 30,000–40,000 m^2 (41–55 per cent aperture efficiencies) were obtained between 38·75 Mc/s and 22 30 Mc/s with effective areas decreasing with increasing zenith angle.

The measured flux densities of the radio sources at the four observational frequencies and their anticipated errors are given in Table 1. Flux densities are given in units of 10^{-26} W m^{-2} (c/s)$^{-1}$. The spectra in the 20–40 Mc/s range of the nine discrete sources observed at Arecibo are shown in Fig. 1. A sample record of an observational scan of the source 3*C*157 is shown in Fig. 2.

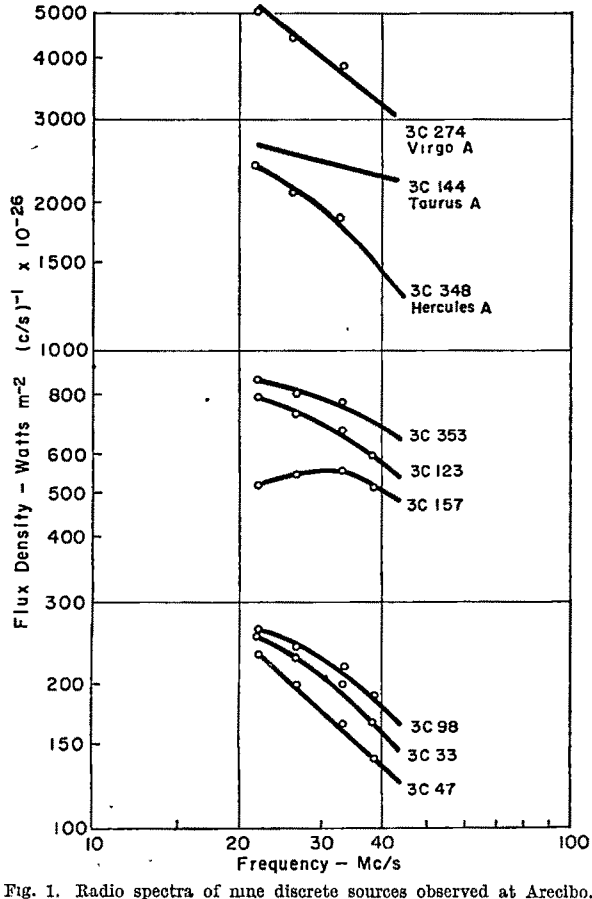

Fig. 1. Radio spectra of nine discrete sources observed at Arecibo. Experimental values are shown as open circles. For calibration purposes, flux density of Taurus *A* was assumed

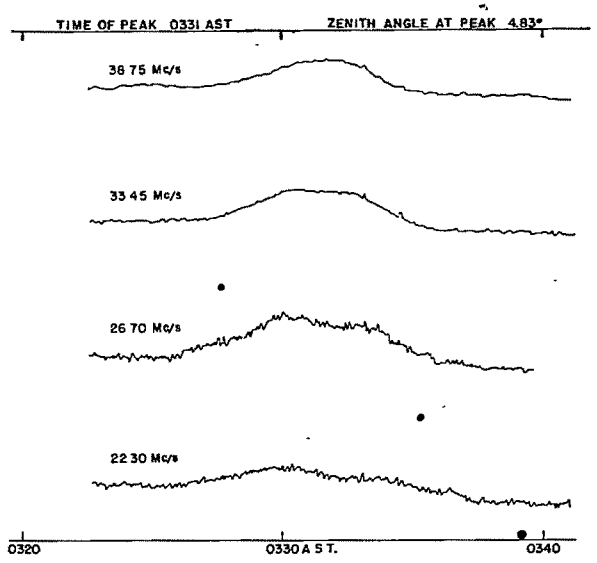

Fig. 2. Declination cut of 3C157 obtained on November 6, 1964. Note the absence of scintillation for this extended source (29′ angular diameter)

Limitations to our work included interference, ionospheric absorption and scintillation, confusion with other sources, and calibration errors. The effects of ionospheric absorption were minimized by operating at night (mainly from 2300 to 0500 h L.T.) during a period of sunspot minimum with small zenith angles. The averaging out of many observations helped to minimize errors due to scintillation. Errors due to confusion were minimized by confining our results to strong, isolated sources which gave clear and repeatable observations. As a check on the consistency of our effective area calibration, a number of observational runs were made on Taurus *A* similar to those made on the other sources and its flux densities calculated using the effective area curves. The difference between the flux densities thus calculated and the assumed values were about 3 per cent.

In Table 1, the error associated with each flux density value is given as the sum of the random measurement error and the precalculated systematic error for each frequency. The systematic errors were calculated as the square root of the sum of the squares of the calibration, confusion, and ionospheric errors. The random measurement errors were determined, under the assumption of normal distribution, from the expression used by Bazelyan[6] and ranged in the order of 1–4 per cent. The errors given do not make allowance for any error in the assumed flux densities of Taurus *A*; however, this should be less than 5 per cent.

Table 1

Source	$S_{22\cdot30}$	$S_{26\cdot70}$	$S_{33\cdot45}$	$S_{38\cdot75}$
3*C*33	259 ± 40	234 ± 35	198 ± 24	169 ± 21
3*C*47	225 ± 35	199 ± 28	168 ± 21	139 ± 20
3*C*98	264 ± 43	241 ± 38	215 ± 28	185 ± 22
3*C*121	795 ± 78	746 ± 69	683 ± 59	616 ± 54
Taurus *A**	2670	2550	2410	2300
3*C*157	521 ± 43	544 ± 39	560 ± 33	517 ± 29
Virgo *A*	5060 ± 500	4458 ± 375	3814 ± 319	—
Herc *A*	2393 ± 245	2124 ± 198	1838 ± 170	—
3*C*353	865 ± 113	818 ± 85	762 ± 79	—

* Assumed flux density on which the flux density determinations of the other sources are based.

Of the nine sources observed, the supernova remnants Taurus *A* and 3*C*157 (*IC*443) have the flattest spectra, with 3*C*157 actually reaching a turnaround point near 30 Mc/s. The source 3*C*157 gave the most consistent results of any source measured; it had random measurement errors of only about 1 per cent and showed no scintillation (because of its 29′ angular diameter[7]). The experimentally observed relationship between scintillation and the angular diameter of the radio source and its application in the determination of the size of night-time ionospheric irregularities has been discussed recently[8].

The steep spectra of the core and halo sources 3*C*47 and 3*C*274 show no appreciable curvature at lower frequencies, while the five other sources, all elliptical or double galaxies, show some degree of convex (downward) curvature. This downward curvature can be explained by the synchrotron self-absorption phenomenon with its increasingly greater effect at lower frequency. The apparent lack of curvature of the core and halo sources may be explained as the counter-balancing result of two effects, synchrotron self-absorption and halo predominance—an effect most prominent in the case of *NGC* 1275[8].

I thank C. Ferioli, W. Kidd, H. Strick and Dr. J. Aarons of the Air Force Cambridge Research Laboratories and the staff of the Arecibo Ionospheric Observatory for their assistance. The Arecibo Ionospheric Observatory is supported by the Advanced Research Projects Agency and is operated by Cornell University under contract with the Air Force Office of Scientific Research.

PHYSICS

Shock Wave from a Release of Gas at 110 km Altitude

AT evening twilight on May 25, 1965, 4·5 kg of gaseous nitrogen dioxide was released at a height of 110 km from the Australian *Aero-High* sounding rocket. Two new observations are reported here. There was a visible glow cloud and, very surprisingly, a wave was observed expanding outwards from the glow. This wave is shown in Fig. 1, which is reproduced from a photograph taken by the Baker–Nunn camera at Woomera 13 sec after release of the nitrogen dioxide. At this time, the diameter of the wave was 11·8 km.

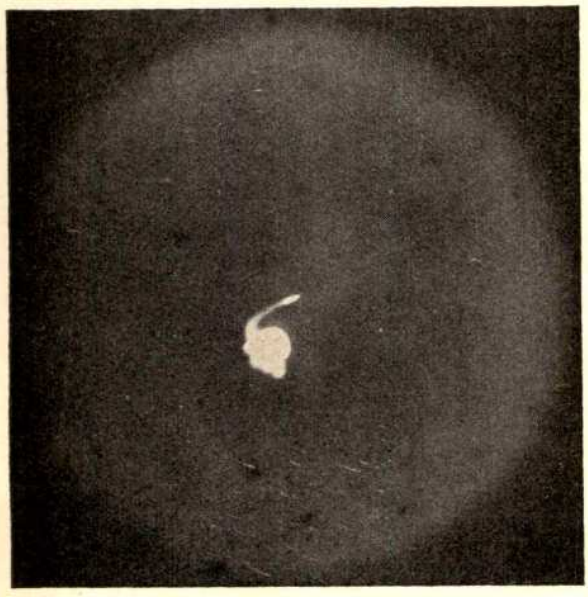

Fig. 1. Glow cloud and wave at +13 sec

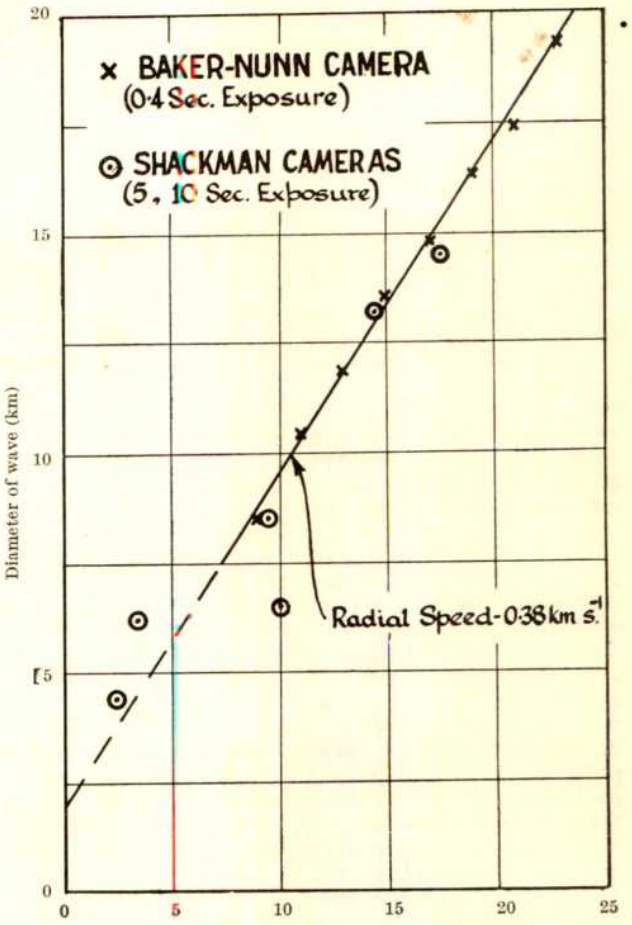

Fig. 2. Variation of wave speed with time

Photographs of the wave enabled diameter measurements to be made for 23 sec and the results are given in Fig. 2. These show that the wave speed became constant, at about 0·4 km sec^{-1}, a few seconds after release of the nitrogen dioxide. The wave is identified as the shock wave because it behaved in the same way as a shock wave formed by the sudden energy release of about 2×10^6 joules, which is the energy arising from this particular gas release. It is interesting to note that similar energy is released by the detonation of a grenade containing 0·2 kg of explosive.

A possible explanation for the detection of the shock wave by our cameras follows from a consideration of sky illumination at the time of observation. The Earth's shadow was at 65 km altitude, which corresponds to an effective shadow height of 90–100 km. In these circumstances, only molecules above 90–100 km altitude scatter significant sunlight at the wave-lengths of interest, and so a weak shock wave of about 10 km diameter near 110 km altitude could produce small, but significant, changes in the distribution of scattering molecules. If this occurred, there would be a detectable change in the radiance of the twilight sky. It follows that a shock wave formed well above the effective position of the Earth's shadow would not be detected because the density decreases by one order of magnitude in a height of about 20 km. Thus shock wave observations over a range of altitudes are possible only if a number of sounding rockets are launched at different times, corresponding to a range of Earth shadow heights.

When the shock wave becomes weak, its speed is constant and equal to the local speed of sound. From Fig. 2 the speed of sound is 380 m sec^{-1}, giving the temperature at 110 km altitude as 340° K.

Nuclear Reactor Operation in Space

RECENTLY, Carpenter, Denfeld and Kronlund[1] estimated that the gamma-rays from a 1 MW (thermal) nuclear reactor operated in space could produce about 5×10^{12} electrons/sec by Compton scattering in the spherical shell of a large heat radiator placed around the reactor; a reactor of radius 0·3 m inside a shell of radius 3·1 m was taken as a possible arrangement. They suggested that these electrons would produce on the shell a positive potential of some 0·8 MV which might affect certain experiments.

We wish to make two comments on their proposal:

(1) At the altitude of 1,000 km, which they assume in their example, the ambient plasma will provide a powerful mechanism for neutralizing the charge on any body within it. Probe measurements with the *Ariel* 1 satellite[2] at altitudes close to 1,000 km have shown electron densities well in excess of 10^3/cm^3 and indeed in many regions the densities exceeded 10^4/cm^3. The effective electron temperature of the plasma is about 2,000° K and hence a flux ($n\bar{v}$) of $2{\cdot}8 \times 10^{10}$ electrons/cm^2 sec will be present even at the low density of 10^3/cm^3. On the elementary model of diffusion, an electron current density of $7{\cdot}0 \times 10^9$ electrons/cm^2 sec would flow on to an uncharged spherical surface, corresponding to a current on to the whole radiator surface (120 m^2) of $8{\cdot}4 \times 10^{15}$ electrons/sec. This is many hundred times greater than the outgoing Compton electron current quoted.

(2) The Compton current of about 0·8 μamp is quite a modest one to generate with a positive ion source which could be used to prevent the build-up of charge, even for a mission into regions of space where the plasma densities are negligible. The ions could be of low energy so that even if they were emitted in excess of the electrons, the potential on the shell would be small. It is also of interest that fast neutrons could be allowed to leak from the reactor and thus produce recoil ions from the shell—an effect which could be enhanced by an external coating of hydrogenous material if energetic protons could be tolerated and if the material could withstand the ambient conditions. A rough estimate of a possible yield of protons can be obtained by assuming that the reactor is designed to give a 10 per cent leakage of fast (fission) neutrons and by allocating an average energy of 1 MeV to them. The recoil protons will have a uniform distribution of energies up to this value and at a particular scattering angle, θ, relative to the neutron direction, the proton energy is given by:

$$Ep = \frac{En}{2}(1 + \cos 2\theta)$$

Thus for $\theta = 30°$, $Ep = 0{\cdot}75$ MeV and the associated range in a material such as polyethylene is about 1·5 m.gm/cm^2. For these protons to escape, irrespective of their points of origin in the shell, the effective shell thickness would have to be $1{\cdot}5 \cos 30° = 1{\cdot}3$ m.gm/cm^2 (the neutrons would arrive approximately radially for the geometry given).

For $\theta = 60°$, $Ep = 0{\cdot}25$ MeV and the associated range is 0·37 m.gm/cm^2. In such conditions the protons must be produced within 0·18 m.gm/cm^2 of the surface to escape and thus, for a converter thickness of 1·3 m.gm/cm^2 only about a seventh of them would do so. At 45° the fraction would be about a half. These values suggest that in this case a reasonable estimate of the proton escape probability will be given by taking it as unity for angles up to 30°, ½ for angles from 30° to 60° and zero above 60°. Thus overall, the fraction escaping would be given, for isotropic scattering in the centre of mass system, by

$$\frac{\int_0^{\pi/6} \sin 2\theta \, d\theta + \frac{1}{2}\int_{\pi/6}^{\pi/3} \sin 2\theta \, d\theta}{\int_0^{\pi/2} \sin 2\theta \, d\theta} = \frac{1}{2}$$

The polyethylene (or similar) converter would have a mean-free-path of about 2·5 gm/cm^2 for n–p scattering at 1 MeV and the scattering rate would thus be about 5×10^{12}/sec for 1-MW operation and 10 per cent leakage. Thus the proton emission would be about $2{\cdot}5 \times 10^{12}$/sec, which is of the same order as the Compton electron emission and it should therefore be possible to design a system to give nearly equal balance between the two and to have a small ion or electron source to produce exact equality. All this assumes that the neutrons, their decay products, the ions and the electrons could be accepted in the space experiments.

Adhesion of Atmospheric Dustfall Particles to a Glass Slide

PARTICLES of atmospheric dust adhere strongly to solid surfaces, as can be judged by the persistence of their presence on automobiles, window ledges and other familiar surfaces. In our laboratory we have for several years been investigating the adhesion of solid particles to various surfaces with the view of clarifying the pertinent influential physical and chemical characteristics of the particle, substrate and ambient air[1–3]. In recent years, several different groups have reported results of measurement of small particle adhesion[4–6]. We were unaware of any previous efforts to measure the forces of adhesion between atmospheric dustfall particles and solid surfaces, or of any investigation that compared the adhesion forces of these particles to other common particle systems of comparable size.

In our investigations two methods are used to evaluate particle adhesion[3]. In the first, particles settle by sedimentation on to a substrate material and the substrate with particles is then mounted in a special holder which fits into the head of an ultracentrifuge. The holders were designed so that centrifugal force on the particles acted perpendicular to and away from the substrate, or parallel to the substrate. In the second apparatus, the substrate with particles was exposed to a high velocity air stream with a well-defined velocity profile. The basis for comparison of strength of particle adhesion was the efficiency of particle removal after exposure to a given centrifugal acceleration or to each bulk stream air velocity. With either technique, it was necessary to examine with a microscope the particle field before and after application of the removal force, that is, centrifugal or air drag. (These procedures have already been described elsewhere[3].)

Clean glass microscope slides were set on the roof of the Graduate School of Public Health in Oakland, Pittsburgh, for 4 h to collect atmospheric dustfall. The slide and deposit were later conditioned for 24 h at 35 per cent or 75 per cent relative humidity (20° C) in a glove box. The results obtained in centrifuge and re-entrainment tests are presented in Table 1 and Table 2, respectively, and are expressed as percentage of particle removed ("Efficiency of Removal") at any stated test condition. The last two columns in Table 1 indicate the centrifugal

forces which were responsible for the noted degree of removal of the spherical glass beads and fly ash particles. These forces were calculated from equation (1) for spherical particles:

$$F_c = m.a.$$
$$F_c = 1/6\pi\, d^3\ \rho\, w^2 R \qquad (1)$$

where F_c is the centrifugal force (dynes), w is the angular speed of rotation (radians/sec), d is the particle diameter (cm), R is the distance from centrifuge axis of rotation to substrate (cm), and ρ is the particle density (1·98 g/cm³ for fly ash and 2·50 g/cm³ for glass beads).

It was not possible to calculate the air drag or adhesion forces for these particles, because the density and shape of atmospheric particles vary over a wide range. For comparison purposes, results for glass beads (A. S. LaPine and Co., Chicago, Illinois) and particles of a Cottrell precipitated fly ash are also shown in Tables 1 and 2. In presenting these results we recognize the great variability in the composition of suspended particulates in urban atmospheres[7] and would anticipate large differences in the adhesiveness of particles collected in different cities, or even at different sites in the same city.

It required bulk stream air velocities as large as 150 m/sec to remove 50 per cent of adhering atmospheric dust particles of 11·5μ projected area diameter. However, it was even more difficult to remove glass beads, but easier to remove fly ash particles, of the same size. In the centrifuge tests, where removal depended on particle weight at any given acceleration, the atmospheric dust particles adhered more strongly than fly ash or glass beads of the same size. Even this generalization is not strictly valid, for with the two smallest sizes of particles (1·3μ and 3·8μ) fly ash adhered most tenaciously. The latter result could be explained by an increase in density of atmospheric particles in the two smallest sizes studied or by alterations in surface properties of particles in this size range. Adhesion of solid particles to solid surfaces is dependent on substrate and particle composition, surface microstructure, and the presence or absence of surface contamination, as well as on other factors[1–6].

Snow and Rain Washout Coefficients for Process Plant Radioiodine Vapour

VERY little is known about the effectiveness of snow in scrubbing the atmosphere, and in the past there have been no reported measurements of the efficiencies with which atmospheric constituents are removed by snow. Theoretical calculations of the collection by raindrops of soluble gases have been reported by Chamberlain[1]; however, similar calculations for snow would require a knowledge of the electrostatic capacitance of the snow crystals and their number per unit volume in air.

A knowledge of the removal efficiencies of atmospheric constituents by precipitation is essential in the investigation of many basic problems in atmospheric physics[2], and the washout coefficients of both gaseous and particulate materials by both rain and snow are being studied. This information is of particular importance in explaining the fall-out rates and mechanisms of airborne radionuclides.

Several experiments to determine the washout coefficients of radioiodine vapour by snow and by rain have been conducted during the past year using the minute amounts of ^{131}I which are present in some stack gas effluents at the Hanford Atomic Plant. The radioiodine in these effluents is all in the vapour state and is about one-half inorganic (hydrogen iodide and $iodine_2$) and half in the form of organic iodides (apparently alkyl iodides)[3].

Experiments were designed to determine the removal of the ^{131}I from the stack plume by comparing the total ^{131}I leaving the stack to the ^{131}I carried down by precipitation in a sampling arc which subtended the plume. The data from these studies were treated in a manner similar

to that used by May[4] in his study of the washout of *Lycopodium* spores.

The quantity of ^{131}I washed out is used to determine the washout coefficient (fraction scavenged per time) for the rain or snowfall, using the following formula:

$$\Lambda = Vy\Sigma c/QtA$$

where Λ is the washout coefficient; V, the wind speed at plume height; y, the distance between samplers; Σc, the total material collected in all samplers, less background; Q, the source release rate; t, the sampling time; A, the area of one sampler.

The sample collectors are 1-sq.-m dishes formed by attaching polyethylene sheets, with some slack, to large hoops made of plastic hose. Fifty to seventy of these are exposed on a line or arc transverse to the stack plume overhead. The collected rain or snow is gathered after a few hundredths of an inch have fallen. There appear to be no splash or residue problems with these simple basins.

The organic and inorganic radioiodine are separated from the melted snow or rain by standard chemical techniques which were modified to accommodate large volumes[5] and are counted in a high sensitivity γ-ray spectrometer[6].

Fig. 1 shows five coefficients for inorganic iodine measured in snowfall, three of these for columnar crystals and two for large, wet agglomerates of spatial dendritic crystals. If crystal size and type were constant in a snowfall, then washout should be linearly related to water-equivalent precipitation rate. Lines of unit slope have been drawn through the data. We assume that there is a family of lines, one for each crystal type, with the position of each line being determined by the velocity and surface area of the crystal.

Also shown are two coefficients measured in rainfall. These values are ten times the theoretical values for iodine vapour washout at these rainfall rates[2]. These measurements were made at different times and processed independently, thus providing a dual verification of the high values. Near the data points are drawn the theoretical washout rates when rain falls through plumes of 20μ and 40μ diameter water drops[2]. Electrical charges on the rain would increase the expected washout by an unknown amount.

Organic forms of radioiodine were scavenged only about 1 per cent as effectively as the inorganic forms, but there was too little captured to allow calculation of coefficients. The rapid scavenging of airborne inorganic radioiodine has been independently observed in condensate from air coolers[7]. Also, the scrubbing efficiency of spray towers for inorganic radioiodine increases with humidity, and Owe Berg attributes this to condensation phenomena[8].

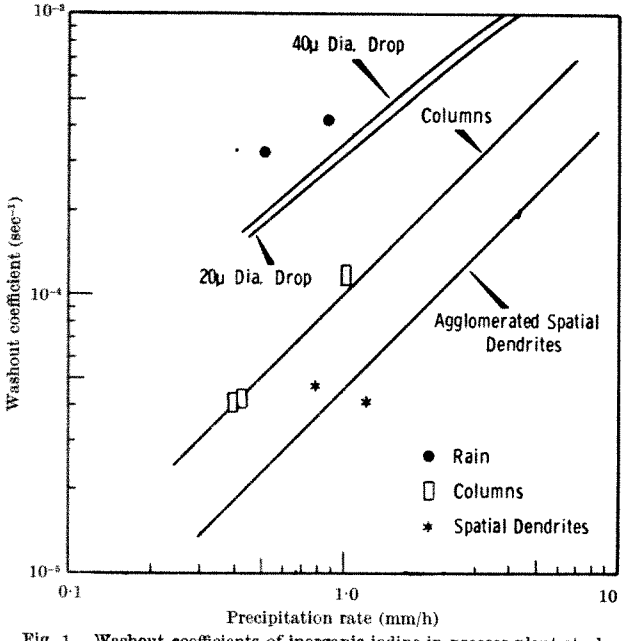

Fig. 1. Washout coefficients of inorganic iodine in process plant stack gases for rain and snow

These process stack plumes at the Hanford Atomic Plant contain sufficient water vapour to produce small water droplets when mixed with cold atmospheric air. Because there appears to be no alternative explanation, we conclude that nearly all the inorganic radioiodine gas is being captured during the water condensation process, as the stack gas mixes with the atmosphere, and that subsequent scavenging occurs at rates appropriate to tiny water drops.

Sub-millimetre Maser Amplification and Continuous Wave Emission

IN our investigations of molecular stimulated emission, we have recently observed amplification by direct current discharges in CN at a wave-length of 0·337 mm. We have also constructed continuous wave oscillator sources of the same wave-length using similar direct current discharges in an apparatus with a plane mirror resonant cavity and beam-splitter coupler as was described earlier[1]. The oscillator discharge tubes were 90 cm long and 5 cm in diameter and were operated under flow conditions, as with pulsed CN masers, at an equilibrium pressure of about 0·1 mm. Typically, the potential drop across the tube carrying a current of 1 amp was 800 V and output powers of the order of 0·1 W have been recorded. Similar results have been obtained using discharges run at 50 c/s. Amplification was observed by means of a similar discharge tube of length 60 cm in the resonant cavity of an independent pulsed CN maser. When a direct current discharge is used in this way, increases of up to a factor of two have been observed in the output power of the pulsed maser.

Pinched Lightning Discharges

THE suggestion contained in my recent letter[1] that pinching out of the discharge may occur on a wide variety of scales from lightning to quasars led to a search of the literature to see if lightning current waves existed which

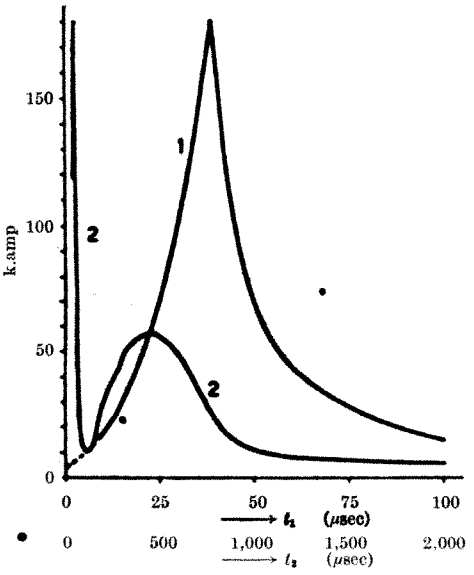

Fig. 1

supported the evidence of the one photograph available of a pinched lightning discharge[2]. The figure shows an oscillogram of the largest lightning current obtained by Berger and Vogelsanger[3] in their investigation of lightning striking their masts on the top of Mount San Salvatore. The similarity to the light curve of Nova Herculis 1934 referred to in the earlier note[1] is quite striking. After rising rapidly to a peak value of 180 kamp, the current fell still more rapidly to 10 k.amp, that is, the discharge was practically extinguished. It then rose again more slowly as the pressure generated by the sudden increase in temperature and by the magnetic pinch effect was released and reached a second peak of 50 k.amp.

A fuller account of the pinching process on this scale is given in a note in the June issue of *Electronics and Power*, in which the light curves of two novae are reproduced for comparison (Fig. 1).

Vibrational Relaxation of Carbon Dioxide in Mixtures with Noble Gases

MEASUREMENTS have been made, using a spectrophone, of the relaxation time of the 4·3μ fundamental vibration of carbon dioxide diluted with the five noble gases—helium, neon, argon, krypton and xenon. The apparatus and experimental procedure have already been described[1].

Calculations based on the Swartz, Slawsky and Herzfield theory (S.S.H.) of collision induced vibrational energy transfer[2,3] show that the asymmetric valence mode of carbon dioxide should relax by a complex process, involving the two lower energy modes, the most likely decay scheme being:

$$h\nu_3 \rightarrow h\nu_2 \;(\text{translation}) \quad + \quad h\nu_1 \rightarrow 2h\nu_2 \;(\text{translation}) \qquad (1)$$

where the frequencies ν_1, ν_2 and ν_3 refer to the symmetric valence, bending, and asymmetric valence vibrations of carbon dioxide respectively, and h is Planck's constant. Because the process $h\nu_1 \rightarrow 2h\nu_2$ is very nearly a resonance exchange it should be very rapid, and the relaxation may effectively be described as the two-step process:

$$h\nu_3 \rightarrow 3h\nu_2 \rightarrow \text{translational energy} \qquad (2)$$

Each of these steps will have its associated rate constant and relaxation time.

For the present results, assuming this model for the relaxation, the relaxation phase lag, γ, between the modulated radiation input and the resulting optic-acoustic pressure fluctuations in the spectrophone can be shown to be approximately[4]:

$$\gamma = \tan^{-1}\left\{\omega\left[\frac{\frac{1}{\tau_1^{AA}}[\chi + g_1(1-\chi)] + \frac{1}{\tau_2^{AA}}[\chi + g_2(1-\chi)]}{\frac{1}{\tau_1^{AA}\tau_2^{AA}}[\chi + g_1(1-\chi)][\chi + g_2(1-\chi)] - \omega^2}\right]\right\}$$

Here τ_1 and τ_2 are the relaxation times of the first ($h\nu_3 \rightarrow h\nu_2$), and second ($h\nu_2 \rightarrow$ translation), steps of the energy transfer process respectively:

$$g_n = \frac{\tau_n^{AA}}{\tau_n^{AB}}$$

The superscripts AA and AB respectively refer to energy transfer in carbon dioxide self-collisions, and in collisions with diluent molecules. χ is the mol fraction of carbon dioxide in the mixture, and ω is the radiation modulation frequency.

Fig. 1 shows typical results of γ versus χ for the five mixtures, at a total mixture pressure of 60 torr and a modulation frequency of 800 c/s. The results strongly support the two-step relaxation scheme, in some cases phase shifts $> \pi/2$ being obtained, which is impossible for a single relaxation process.

Perhaps the most interesting feature of the results is the collision reduced mass dependence of the relaxation time. To analyse this, it is necessary to know the relative values of g_1 and g_2 for the first and second steps of the relaxation. Because the latter involves the de-excitation of the bending mode, values of τ^{AA}/τ^{AB} obtained from ultrasonic absorption and velocity measurements, or from spectrophone investigations using the 15-μ vibration band, should correspond to g_2. Values for carbon dioxide–helium and carbon dioxide–neon mixtures are available from Cottrell and Day[5], for carbon dioxide–argon from my own spectrophone results. Using these values for g_2, corresponding values of g_1 were calculated from the data. The results are given in Table 1.

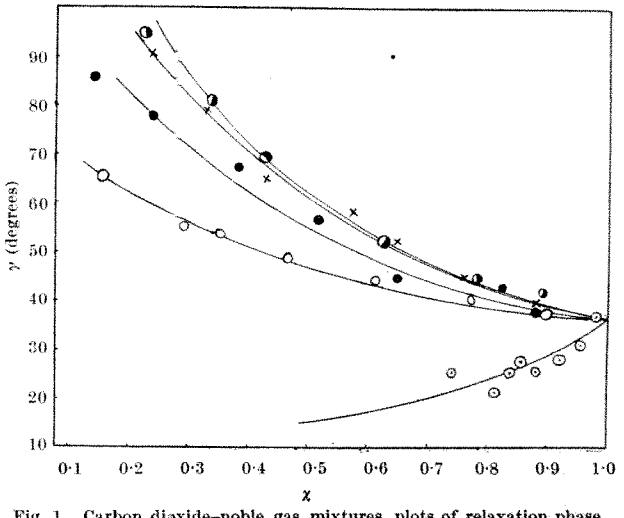

Fig. 1. Carbon dioxide–noble gas mixtures, plots of relaxation phase lag (γ) against carbon dioxide mol fraction (χ). Solid lines represent best fit of equation 2 to data for g_1 equals g_2. ⊙, Helium; ○, neon; ●, argon; ×, krypton; ◑, xenon

Table 1

Diluent	g_1	g_2
Helium	14	2
Neon	0·5	0·3
Argon	0·1	0·14
Krypton	0·028*	0·067*
Xenon	0·0167*	0·055*

* Values obtained by extrapolation of plots in Fig. 2.

If $\bar{P}_{10}$ is the probability of de-excitation/molecule/collision, simply related to the relaxation time by:

$$\bar{P}_{10} = \frac{\tau_c}{\tau(1 - e^{h\nu/kT})}$$

where τ_c is the average time between collisions, then the S.S.H. theory gives the dependence of $\bar{P}_{10}$ on μ as:

(Mass dependent pre-exponential factor) $\times$ exp.$(-B\mu^{\frac{1}{3}})$ where:

$$B = \frac{3}{2}\left(\frac{16\ \pi^4\ \Delta E^2}{\alpha^2 h^2\ kT}\right)^{\frac{1}{3}}$$

Here ΔE is the energy to be exchanged with translation, and α is the intermolecular force range parameter. The pre-exponential factor varies with the type of colliding molecule, but basically has the form of the product of μ^2 and a factor mainly dependent on the masses of the atoms constituting the relaxing molecule. This factor (A) will remain fairly constant for all the mixtures investigated. Thus taking the reduced mass dependence to be of the form:

$$\bar{P}_{10} = A\mu^2 \exp\left(-B\mu^{\frac{1}{3}}\right) \qquad (3)$$

where A is independent of μ. Fig. 2 shows a plot of:

$$\left[\log_e \frac{(\bar{P}_{10}^{AB})}{(P_{10}^{AA})} - 2\log \mu\right]$$

against $\mu^{\frac{1}{3}}$ for the present results. Agreement is excellent for the limited data. Extrapolation of the graphs, to obtain g_1 and g_2 for krypton–carbon dioxide and xenon–carbon dioxide mixtures, yields values which when substituted into equation (2) give a good fit to the experimental results for these mixtures.

The results show that the relative inefficiency of the noble gases at de-exciting carbon dioxide vibrations, compared with carbon dioxide itself, already noted in measurements on the bending vibrations[5,6] is confirmed for both stages of the relaxation of the asymmetric valence mode. The noble gases, as a group, give a reduced mass dependence of the carbon dioxide relaxation in good agreement with present-day theory. Making the assumption that α is constant for the five mixtures, and taking values for ΔE of 500 k and 960 k for the first and second steps of the relaxation, the slopes of the Fig. 2 plots give values for α of $5{\cdot}2 \times 10^8$ cm^{-1} and $5{\cdot}8 \times 10^8$ cm^{-1}, respectively.

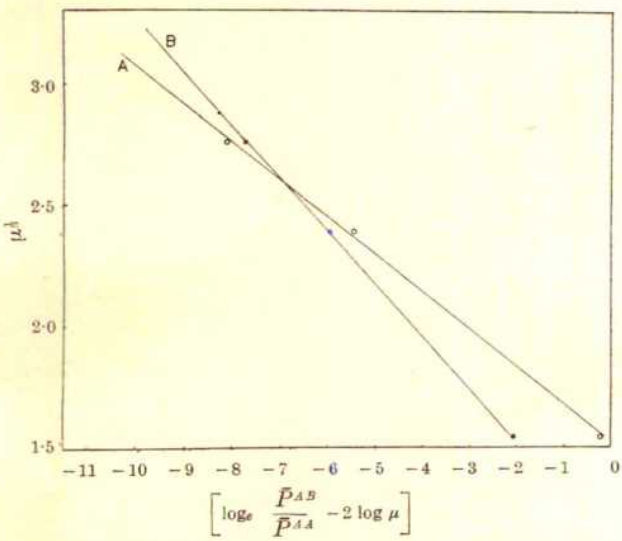

Fig. 2. Plots of $\log_e \frac{\bar{P}^{AB}}{\bar{P}^{AB}} - 2\log \mu$ against $\mu^{1/3}$ for the first (plot B) and second (plot A) steps of the relaxation of the ν_3 mode of carbon dioxide in mixtures with helium, neon and argon

As can be seen from Fig. 2, self-collisions between carbon dioxide molecules do not follow this simple mass dependence. The relatively simple collision between an atom and a triatomic molecule would seem more likely to agree with the predictions of approximate theories like the S.S.H. than that between two triatomic molecules, where unknown orientation or rotational factors may be important.

CHEMISTRY

Structure and Formation of Magnesium Oxychloride Sorel Cements

THE hardening process by which a cement is formed from a polycrystalline matrix has been investigated using a cement of relatively simple composition and structure—Sorel cement[1]. This cement is formed by the addition of magnesium chloride solution to a fine powder of magnesium oxide[2]. The viscous paste hardens on drying and sets to a cement consisting of a mass of needle-like crystals of $Mg_3(OH)_2Cl{\cdot}4H_2O$. The appearance of the cement is shown in Fig. 1, which was taken with a scanning electron microscope (by A. Rezanowich and I. Frazer at the Pulp and Paper Research Institute, Montreal).

Figs. 2 and 3 are transmission electron micrographs of a cement specimen prepared in a dilute solution. These

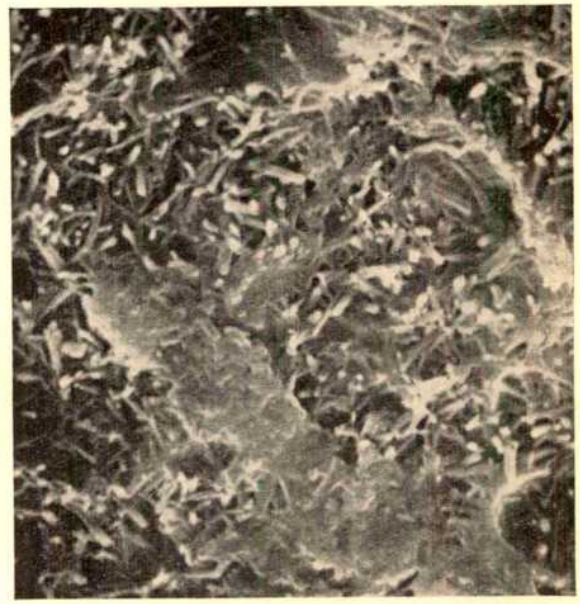

Fig. 1. A micrograph of a fractured surface of magnesium oxychloride cement taken on a scanning electron microscope. (×2,975)

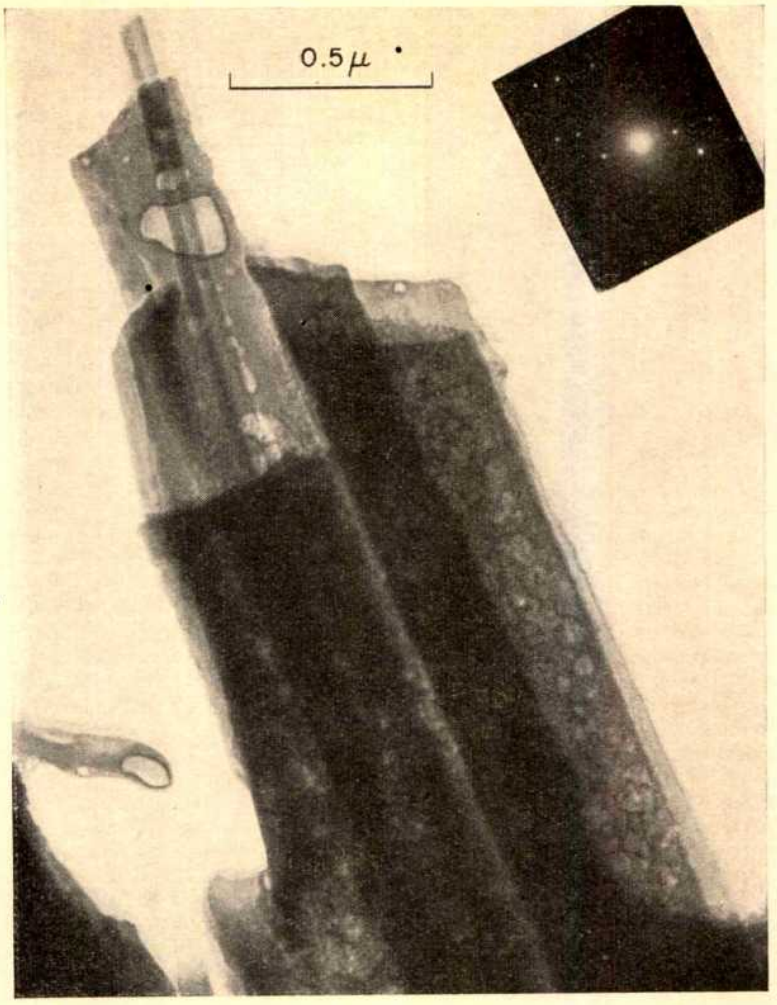

Fig. 2. Typical scroll-whiskers of magnesium oxychloride. The diffraction pattern displays layer lines typical of a rotation pattern, indicating the cylindrical nature of the crystals. The crystals have undergone some thermal etching in the electron beam in the microscope

micrographs show the needles of the oxychloride to be scroll-tubular whisker crystals, similar in many ways to those of graphite[3]. The structure of magnesium oxychloride[4] consists of puckered planes of Mg-O octahedra parallel to the needle or *b*-axis, separated by (100) planes of water and chlorine, so that these (100) planes are weakly bonded and stack without complete periodicity. Dehydration studies in the electron microscope also emphasize the scroll-tubular whisker nature, and indicate that the other hydrates of the oxychloride, in particular the $3H_2O$, have a similar structure (to be reported elsewhere).

In Fig. 3, two crossing magnesium oxychloride crystals are seen which either interpenetrate or have enhanced growth at the point of contact[3]. Partially unwound scrolls are frequently seen as well as highly curved whisker and tape crystals. In Fig. 4, where the specimen stood several days in the laboratory on the electron microscope grid, thin leader crystals can be seen in the micrograph similar to those observed from sodium chloride[3]. These leader crystals curve and interweave from one crystal group to another.

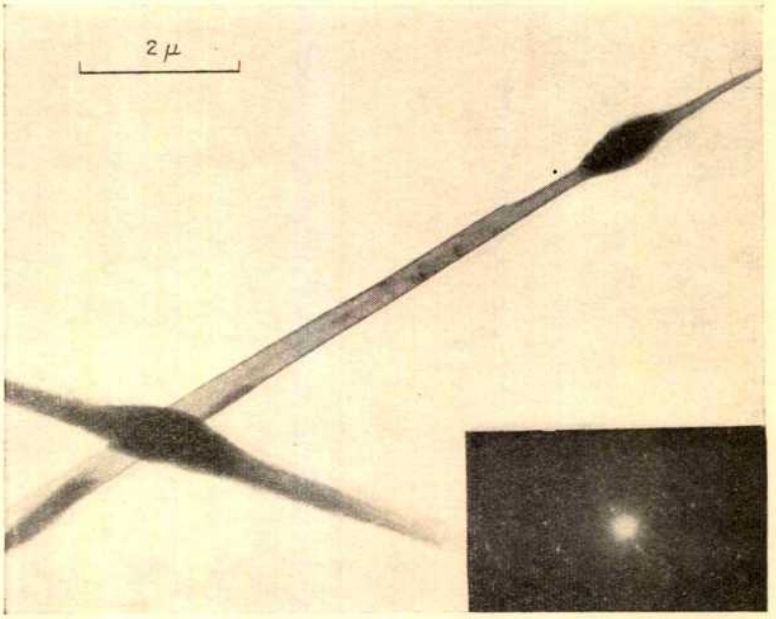

Fig. 3. Two needle-crystals of magnesium oxychloride crossing, possibly interpenetrating, with enhanced growth at the point of contact. Both crystals display features of scroll-type whiskers

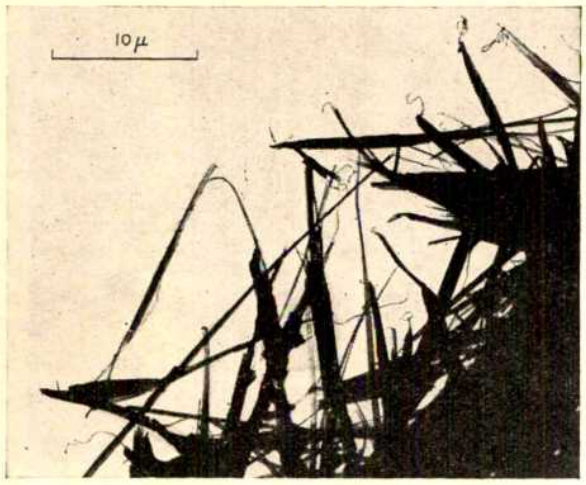

Fig. 4. Very thin crystals grow from the original crystals in the magnesium oxychloride cement after several days

The hardening process and formation of a cement can be interpreted in terms of these structural features as follows. Whisker crystals of the hydrates grow on the magnesium oxide crystals, which are prepared by a particular heat treatment of magnesium carbonate[2] and are thus likely to contain many crystal imperfections as sites for whisker growth. The whisker crystals are very strong and bond together mechanically. Further bonding occurs by the presence of unwound scroll crystals, as well as by the interpenetration of crystals, enhanced growth where crystals touch, and winding leader crystals.

A relationship can be seen to the scroll nature postulated and observed for tobermorite crystals in Portland cement pastes[5]. Some fine needle crystals have also been observed in some zinc phosphate preparations, which indicates that a similar structural mechanism may apply for zinc phosphate (dental) cements.

Other cements of structures related to magnesium oxychloride hydrate are suggested and cements have been formed from NH_4CdCl_3 and $K_2SnCl_6 \cdot 2H_2O$. Many other compounds containing infinite chain ions may also form cement materials, provided they crystallize in a suitable whisker form. In general, knowledge of whisker crystal growth and behaviour, such as growth promotion from porous substrates[3,6], can be used with advantage to develop properties and formation of cements.

Examination of Surfaces by scanning with Charged Particles

A STUDY of the distribution of elements in inhomogeneous samples has assisted many chemical and metallurgical investigations, and in particular the electron probe microanalyser has proved a valuable tool for examining small areas at high resolution. In certain cases, however, a less costly analytical instrument of lower resolution is required for scanning larger areas, and for this purpose an X-ray milliprobe analyser has been designed, using a collimated beam of X-rays 1 mm in diameter[1].

We have described recently a number of analytical methods based on the measurement of γ-radiation emitted during the rapid decay of excited nuclear states formed as the result of charged-particle bombardment[2]. This procedure lends itself readily to the analysis of localized areas of a sample, since the low depth of penetration of charged-particles limits reaction to that part of the target near to the surface, and measurement of prompt γ-radiation permits simple use of a scanning technique. The method is particularly suitable for measurement of light elements, which are the most difficult to determine by X-ray methods.

The feasibility of examining surfaces by charged-particle scanning has already been briefly discussed[3,4], but we now report specific results obtained from scanning several test samples. Synthetic samples were chosen so that their known structure could be compared with that indicated by the scanning results.

A beam of protons accelerated to 1·80 MeV by a 2-MeV Van de Graaff electrostatic generator was collimated by an aperture 0·66 mm in diameter in a tantalum stop, and the beam current maintained at about 0·008 μamp. Targets were secured to a table which could be traversed in two directions at right angles to each other and the proton beam. Adjustment in one direction was relatively coarse, and once set was not changed during a scan; a micrometer-screw was used to move the target a known distance in the other direction between irradiations.

γ-Rays emitted by the target during irradiation were detected by a 3 in. × 3 in. thallium activated sodium iodide scintillator, and after amplification the output was fed to a 100-channel pulse–height analyser, controlled from the beam current integrator to permit the count to be totalled while the sample was irradiated to a pre-set proton dose. After each irradiation, which lasted about 5 min, the channel contents of the analyser, real and live times, were recorded, the micrometer adjusted and another irradiation started.

Targets were sheets of aluminium sandwiched between copper. One face of each target was machined flat, polished and etched, and mounted in the specially constructed target holder in order to traverse a copper–aluminium–copper section with the proton-beam.

The most intense prompt γ-ray from the reaction of 1·80-MeV protons with thick targets of aluminium has an energy of 0·84 MeV, corresponding to the decay of the first excited state of aluminium-27 produced by the inelastic scattering reaction $^{27}Al(p,p')^{27}Al$. Fig. 1 shows the variation in the detected yield of the 0·84-MeV γ-ray as each of three samples was passed across the proton-

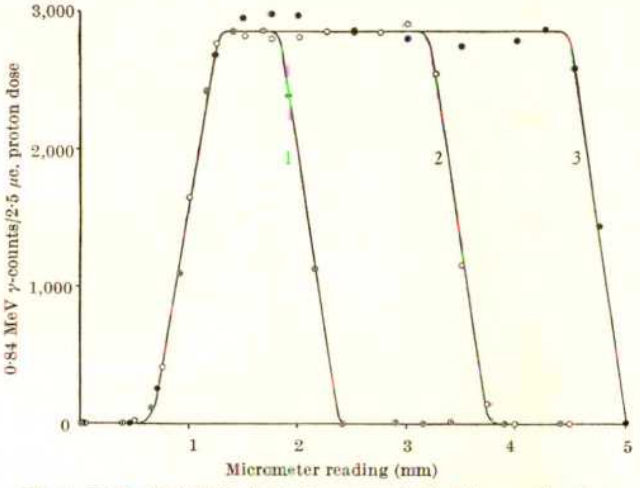

Fig. 1. Yield of 0·84-MeV aluminium γ-rays obtained by scanning three different copper–aluminium–copper targets with 1·80-MeV protons

beam. As the copper–aluminium interface was traversed, the count-rate increased to reach a constant value when the entire beam was collected on the aluminium section. The length of the plateau was determined by the thickness of the aluminium sheet, and in Table 1 widths calculated from half-height are compared with values measured optically with a travelling microscope. It can be seen that the agreement is good.

Table 1. WIDTH OF ALUMINIUM SHEETS IN TARGETS

Sample	Optical measurement (mm)	Proton scan (mm)
1	1·14	1·13
2	2·52	2·50
3	3·87	3·75

In these experiments, the minimum time required for an irradiation was governed by the long dead-time of the multi-channel analyser (900 μsec). If a faster analyser had been available, it would have been possible to reduce the irradiation time by using a higher beam-current, and taking advantage of the higher yield of 0·84-MeV γ-rays obtained on increasing the proton-energy.

Aluminium was scanned in this work because it can easily be incorporated in targets as sheets of known thickness, but particle scanning can equally well be applied to the determination of any element which can be measured by a prompt-radiation technique similar to that described for aluminium. By careful choice of bombarding-particle and energy, and with the aid of γ-ray spectrometry, methods are available for most of the light elements.

We thank H. D. Hitchcox and M. E. Thompson for construction of the target assembly and preparation of the targets, and B. Morris for operating the accelerator.

Iron Enneacarbonyl

AT various times[1] doubt has been expressed as to the authenticity of iron enneacarbonyl, $Fe_2(CO)_9$, owing to its low solubility in all solvents and apparent lack of volatility. We have therefore carried out an investigation of this carbonyl, which was made by exposing iron pentacarbonyl, sealed under high vacuum in 'Pyrex' vessels, to sunlight; tri-iron dodecacarbonyl, which also formed in small amounts[1], was removed by repeated washings with petrol ether. A series of analyses on different samples of iron enneacarbonyl clearly indicates that the empirical formula is $Fe_2(CO)_9$. (Found (per cent): carbon, 29·9, 29·7, 30·2, 29·6; oxygen, 39·2, 38·0, 39·4. Calculated (per cent) for $C_9O_9Fe_2$: carbon, 29·7; oxygen 39·6.)

Although it is stated that iron enneacarbonyl is involatile[1], we have observed that under a good vacuum (10^{-5} to 10^{-6} mm) it will sublime at about 70° C to form hexagonal-shaped crystals. The sublimation occurs cleanly if the enneacarbonyl has been dispersed, by crushing and rubbing, against the apparatus walls, but attempts at the sublimation of bulk samples cause rapid decomposition and the formation of an iron mirror; volatility comparisons to the other metal carbonyls, including tri-iron dodecacarbonyl, suggest a molecular weight higher than that corresponding to $Fe_2(CO)_9$. However, the mass spectrum, obtained under conditions such that the enneacarbonyl was introduced into the electron beam at room temperature to minimize any possible thermal decomposition, definitely shows the molecular ion $Fe_2(CO)^+_9$ centred at mass 364 and has no peaks of higher molecular weight; furthermore, none of the ions formed on fragmentation contains more than two iron atoms. An interesting fact which emerges from a study of the mass spectrum is that the peak due to $Fe_2(CO)^+_3$ is the most intense of the $Fe_2(CO)^+_x$ ions. An attractive explanation for this is that the three carbon monoxides represent the bridging carbonyl groups in the original iron enneacarbonyl because it seems reasonable to assume these particular carbonyls (which are bonded simultaneously to the two iron atoms) will be less readily lost on fragmentation of the molecule than the terminal carbonyl groups. This work, therefore, substantiates the formulation of iron enneacarbonyl, but in no way explains the unusually low solubility and volatility for a compound of such low molecular weight.

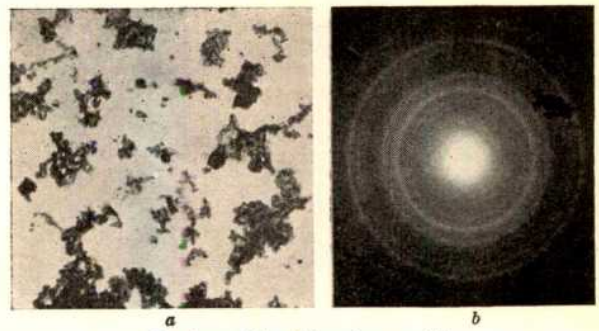
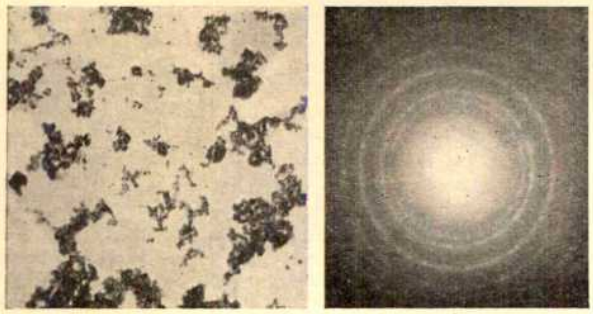
Decomposition of Ferrosic Sulphide to Pyrrhotite in an Electron Microscope



FRAGILE compounds undergo thermal decomposition in an electron microscope in which specimens are exposed to a high vacuum and to electron bombardment[1–5].

Ferrosic sulphide with a spinel structure has just become recognized as a well-defined compound since Skinner *et al.*[6] recently discovered mineral greigite. They have observed the thermal breakdown of greigite to pyrrhotite and pyrite at 320° C in a sealed, evacuated silica tube. In contrast with their result, the decomposition of ferrosic sulphide to pyrrhotite and sulphur vapour occurred when the specimen was heated above 300° C in a vacuum with the pump operating.

It was interesting to see if the same experimental condition could be achieved in an electron microscope, enabling one to follow the crystallographic and morphological changes during the decomposition.



In a previous paper[7], a synthetic method of ferrosic sulphide is described in some detail. The powder particles of the ferrosic sulphide were mounted on a specimen grid covered with a collodion film. The crystals were examined in a Hitachi *HS-7* electron microscope operated at 50 kV. The $L\lambda$ values (L is the effective camera length and λ is the electron wave-length) were determined with a gold foil standard.

Electron micrograph and diffraction patterns at the initial stage were recorded, care being taken not to subject the specimen to more than the minimum beam intensity.

a *b*

Figs. 1*a* and 1*b*. Before decomposition

a *b*

Figs. 2*a* and 2*b*. After decomposition. Wave-length of the electron beam was 0·0548 Å. (×15,000)

In order to decompose the specimen, the beam intensity was gradually increased by controlling a condenser lens. A set of micrographs and diffraction patterns taken before and after decomposition are shown in Figs. 1*a*–2*b*. The original diffraction pattern is identified with that of ferrosic sulphide with a spinel structure of $a = 9{\cdot}90$ Å. The final pattern can be indexed for a hexagonal lattice with $a = 3{\cdot}43$ and $c = 5{\cdot}68$ Å corresponding to the value expected for pyrrhotite. The original particles of ferrosic sulphide are visible in Fig. 1*a*, but the contrast between them and the background is small. During decomposition the shape and the size of the particles remain almost invariable, though the contrast and transparency of the specimen increase in some degree. This is presumably because the ferrosic sulphide loses sulphur as vapour and thereby alters its form to pyrrhotite, the density of which is greater than that of ferrosic sulphide.

Ion Exchange Method of estimating Strontium-90 and Other Radionuclides in Rainwater

THE collection of bulk samples for the assay of radioactivity in rainwater involves the handling and preparation of large volumes of water. The need to reduce this work, together with a desire to achieve greater sensitivity and more specific data on the distribution of radionuclides in rainwater, has led to the development of the following method of collecting rainwater.

The apparatus is based on an idea of Boni[1], and incorporates a technique for separating caesium-137 described by Morgan and Arkell[2]. It is contained in a wooden box, 5 ft. high × 1 ft. square section, on top of which is a rainwater collection pan 18 in. square with a hole 1 in. in diameter in the centre. The components of the apparatus are mounted vertically and centrally in the box, which is fitted with a door which is normally closed. To obviate freezing of the columns during cold weather, two electric light bulbs (100 W) are placed beside the ion exchange columns.

The column components (see Fig. 1) from top to bottom are: asbestos pad (1½ in. diameter × ¼ in. thick) to remove particulate matter; ammonium-12 molybdophosphate (AMP)/asbestos pad (1½ in. diameter × ½ in. thick) for caesium-137 estimation (the ammonium-12-molybdophosphate used is prepared according to the method of Smit *et al.*[3], which gives a fine crystalline product, and this is mixed with an equal weight of asbestos fibre to obtain satisfactory porosity); anion resin column (1 in. diameter × 6 in. long, 'De-Acidite *F.F.*' *S.R.A.* 69. −14 + 52 mesh $[OH]^-$); cation resin column (1 in. diameter × 6 in. long, 'Zeo-Karb 225'. *SRC* 19. 100–200 mesh $[H]^+$). All columns are glass and the connexions between them are made by rubber bungs and sleeves.

The effluent from the cation column is passed into a 10-l. storage bottle through a constant head device to prevent the columns running dry. The purpose of the storage bottle in this initial study was to check for radionuclides which may have escaped retention on the columns. In fact, no such activity was detectable. During normal operation the effluent from the columns runs to waste and a standard rainwater gauge is used to measure rainfall.

The various components of the apparatus were separated at the end of each sampling period (1 month) and analysed for strontium-90. The ammonium-12-molybdophosphate/asbestos pad was washed with 2 N ammonium nitrate solution followed by 0·01 N nitric acid to remove the strontium-90, which was then precipitated as carbonate from the wash solution together with added stable strontium carbonate carrier (85 mg), then chemically separated and purified by the standard fuming nitric acid technique[4]. The equilibrated yttrium-90 daughter was separated and counted by anti-coincidence low background technique.

The washed ammonium-12-molybdophosphate/asbestos together with the two ion exchange resins and the asbestos particulate filter were counted by γ-spectrometry.

The strontium-90 was removed from the ion exchange resins by leaching with 8 N nitric acid, precipitated as carbonate together with added stable strontium carbonate carrier (85 mg); and then treated identically as described for ammonium-12-molybdophosphate wash solution.

The γ-ray spectrometer analyses of the activity on column components showed that most of the caesium-137 was retained by the ammonium-12-molybdophosphate/asbestos pad, although in some cases part of it was etained by the particulate filter.

Table 1 summarizes the results of the strontium-90 analysis of the column components over the period June 1964–February 1965. Also included are the comparative results for rainwater analysed on a routine basis over the same period.

As additional information, Table 2 shows a typical distribution of various γ-emitting radionuclides in 1 month

Table 2. TYPICAL γ-SPECTROMETRY ANALYSES OF RAINWATER

Isotope	Particulate filter	AMP/ asbestos pad	μμc./l. Anion resin	Cation resin	Column effluent
Ruthenium-106	70	—	15	—	—
Cerium-144	141	—	—	—	—
Caesium-137	18	40	—	—	—
Zirconium-95/ niobium-95	3	—	24	—	—
Mercury-203	—	—	Trace	—	—
Manganese-54	—	—	—	3	—

during the same period. Ruthenium-106 was distributed between the particulate filter and the anion column; caesium-137 between the particulate filter and the ammonium-12-molybdophosphate/asbestos pad; zirconium-95/niobium-95 on the anion resin.

It is interesting to note that all the cerium-144 and a high percentage of the other radionuclides were retained on the particulate filter.

It can be concluded that: (1) Caesium-137 was retained specifically by the ammonium-12-molybdophosphate/asbestos pad, provided it passed the asbestos particulate filter. (2) Some strontium-90 was loosely held by the ammonium-12-molybdophosphate/asbestos pad, but most of the remainder was retained by the cation resin. (3) The total strontium figures compare favourably with the routine district survey figures, the differences in most cases being accountable for by the precision of the counting procedure.

If the ammonium-12-molybdophosphate stage were omitted, it seems reasonable to suggest that almost all the strontium-90 would be retained by the cation resin. In these circumstances the method would be specific for strontium-90.

Lewis and Bronsted Acid Sites on Silica–Alumina

SOME years ago, Mapes and Eischens[1], Nicholson[2] and Roev, Filimonov and Terenin[3] studied the infra-red spectrum of ammonia chemisorbed on silica–alumina cracking catalysts. Mapes and Eischens[1] reported absorption bands at 3,330 cm^{-1} and 1,640 cm^{-1} which were assigned to ammonia adsorbed on Lewis (electron acceptor) acid sites. In addition weak bands were observed at 3,030 cm^{-1} and 1,450 cm^{-1}, which were attributed to NH_4^+ ions formed by chemisorption of ammonia on Bronsted (proton donor) sites. From the relative intensities of the bands, Lewis sites were thought to predominate on dehydrated silica–alumina although adsorbed water was observed to cause conversion of Lewis to Bronsted sites. Nicholson[2] only investigated the spectrum in the region of NH stretching vibrations and reported approximately equal numbers of Lewis and Bronsted sites. However, Roev *et al.*[3] observed only ammonia on Lewis acid sites for their sample of silica–alumina.

Since that time Parry[4] and Basila, Kantner and Rhee[5] have investigated the chemisorption of pyridine and have established conclusively the existence of both Lewis and Bronsted sites on silica–alumina. However, as the results for the chemisorption of ammonia have been widely quoted we have repeated the experiment using an improved technique. Our results, which differ significantly from those of the earlier workers, are presented here.

The sample of silica–alumina (a commercial Esso cracking catalyst) had an alumina content of 25 per cent and a surface area of about 250 m^2/g. It was ground to a fine powder and compressed to a thin disk under a pressure of 10 tons/in.^{2}. The disk was mounted in a vacuum cell and all spectra were recorded without disturbing the alignment in the infra-red beam of the spectrometer. The spectra shown in Fig. 1 were recorded on a Perkin Elmer model 521 spectrometer using the linear absorbance attachment. The sloping backgrounds of the spectra were caused by scattering by the sample disk. An attenuator was placed in the reference beam to compensate for these radiation losses. It was periodically adjusted to maintain the trace from the spectrometer on the chart paper. This procedure caused the discontinuities in the spectra.

Fig. 1*a* shows the spectrum of a disk of silica–alumina after evacuation at 450° C. It is very similar to those given by Basila *et al.*[5]. The spectrum of Fig. 1*b* was obtained after the disk was exposed to 5 cm of ammonia gas and then evacuated for 1 h at 25° C to remove physically adsorbed ammonia. We interpret these spectra as follows. Ammonia chemisorbed on surface Lewis sites has absorption bands at 3,335 cm^{-1}, 3,280 cm^{-1} and 1,610 cm^{-1}. Some ammonia is also chemisorbed on Bronsted sites as NH_4^+ ions which absorb at 3,270 cm^{-1} and 1,440 cm^{-1}. This means that in the region of NH stretching vibrations the bands of both adsorbed species overlap. No bands are observed near 3,000 cm^{-1} where both Mapes and Eischens[1] and Nicholson[2] reported absorption by NH_4^+ species. However, our assignment of a band at 3,270 cm^{-1} to an ammonium species is in agreement with the assignment of Mortland, Fripiat, Chaussidon and Uytterhoeven[6] for ammonium ions on montmorillonite.

Addition of water vapour to the sample followed by evacuation for 1 h at 25° C (Fig. 1*c*) resulted in removal of the bands at 3,335 cm^{-1}, 3,280 cm^{-1} and 1,610 cm^{-1}, and an increase in the intensity of bands at 3,270 cm^{-1} and 1,450 cm^{-1}, that is, ammonia adsorbed on Lewis sites has been converted to ammonium ions. From the intensity changes of the bands at 1,610 cm^{-1} and 1,440 cm^{-1} following the addition of water, it is estimated that for dehydrated silica–alumina the ratio of the number of Lewis to Bronsted acid sites lies between 1 : 1 and 3 : 2. Basila *et al.*[5] estimated a similar ratio from their results for pyridine chemisorption. The weak band at 1,680 cm^{-1} in Fig. 1*c* may be due to the ν_2 bending mode of NH_4^+

which Uytterhoeven, Christner and Hall[7] observed at 1,680 cm^{-1} for ammonium ions on decationated *Y*-type zeolites.

After completing the adsorption of ammonia the silica–alumina sample was evacuated at 450° C and a spectrum similar to Fig. 1*d* obtained. Admission of water vapour to the sample followed by evacuation at 25° C gave the spectrum of Fig. 1*e*. Absorption bands appear at 1,630 cm^{-1} due to the deformation vibration of water molecules and at about 3,500 cm^{-1} due to water stretching vibrations. The exact frequencies of the latter vibrations are uncertain because of the contribution of hydrogen bonded surface hydroxyl groups to absorption in this region.

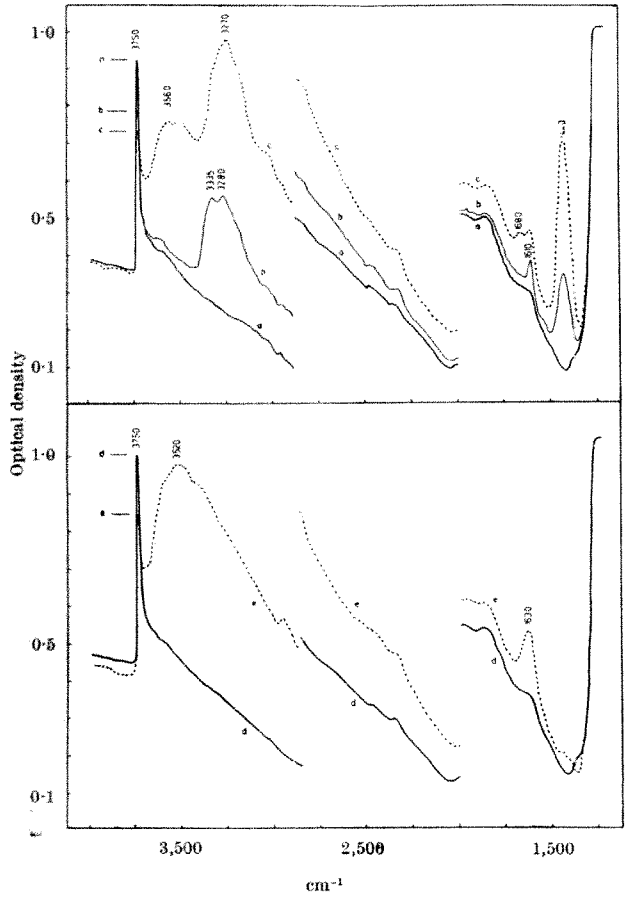

Fig. 1. The infra-red spectrum of silica–alumina with adsorbed ammonia and water: *a*, after evacuating the silica-alumina at 450° C; *b*, after adsorbing ammonia and evacuating at 25° C following *a*; *c*, after adding water vapour and evacuating at 25° C following *b*; *d*, after evacuating at 450° C following *c*; *e*, after adding water vapour and evacuating at 25° C following *d*. The horizontal lines on the spectra *a* – *e* mark the optical density of the 3,750 cm^{-1} band due to isolated surface hydroxyl groups

Fig. 1*c*, which was obtained after evacuation of water from the ammonia covered sample, shows a weaker band at 1,630 cm^{-1} than that given in Fig. 1*e*. This observation is consistent with the following reaction:

$$H_2O + H_3N : \text{Lewis acid} \rightarrow OH^- + NH_4^+ \text{ (ads)}$$

Since the water molecule is no longer present, no band due to its deformation vibration should be expected. The band of reduced intensity at approximately 3,500 cm^{-1} in Fig. 1*c* then originates from the OH$^-$ ion produced by the foregoing reaction, from some water molecules contributing to the weaker band at 1,630 cm^{-1} and from surface hydroxyl groups involved in hydrogen bonding.

One of us (N. W. C.) acknowledges the help of a C.S.I.R.O. studentship. We thank the Australian Institute of Nuclear Science and Engineering for a grant to purchase the spectrometer.

CRYSTALLOGRAPHY

Crystal Structure of Caesium Permanganate

IN investigations of the effect of high-energy radiation on crystals of the permanganates of the alkali metals, a knowledge of the crystal structure of caesium permanganate is required. The only previous investigation of this substance was by Muthmann[1], who, using optical goniometric methods, determined the axial ratios as: $a : b : c = 0{\cdot}8623 : 1 : 0{\cdot}6853$.

We obtained crystals (0·1 × 0·2 × 0·4 mm) of caesium permanganate from an aqueous solution containing stoichiometric amounts of caesium nitrate and potassium permanganate. The axial ratios were determined by optical goniometry as $a : b : c = 1{\cdot}734 : 1 : 1{\cdot}370$. Muthmann's values must have been obtained by using incorrect Miller indices, since with our results, and his indexing, we obtain the values of $a : b : c = 0{\cdot}867 : 1 : 0{\cdot}685$. These compare reasonably well with his.

The Laue symmetry was confirmed by X-ray methods as *mmm*. The unit cell dimensions were obtained from Weissenberg zero-level photographs using filtered CuK_α radiation. The method of Farquhar and Lipson[2] was used, except that the lattice parameter under investigation was plotted against $\cot\theta \cos^2\theta$ because of the high absorption of the crystals. The parameters obtained were:

$$\begin{aligned} \text{Orthorhombic: } a &= 10{\cdot}0692 \pm 0{\cdot}0005 \text{ Å} \\ b &= 5{\cdot}8080 \pm 0{\cdot}0005 \text{ Å} \\ c &= 7{\cdot}9470 \pm 0{\cdot}0005 \text{ Å} \end{aligned}$$

The axial ratios computed from these values are:

$$a : b : c = 1{\cdot}7337 : 1 : 1{\cdot}3683$$

The number of formula units per unit cell, using $d = 3{\cdot}597$ g/c.c., is four.

An investigation of systematic absences in zero- and upper-layer Weissenberg photographs taken with the crystal oscillating about the three principal axes gave the diffraction symbol as *mmmPna*-. This indicates two possible space groups, namely, *Pnma* or $Pna2_1$. By analogy with the corresponding potassium compound[3], and considering the consequent successful structural analysis, the correct space group is *Pnma*.

The Patterson projection on (010) was evaluated and the minimum functions M_2, M_4 and M_8 were set up. The preliminary positions of the manganese and caesium atoms obtained from these were used to calculate successive difference Fourier syntheses. For the third and fourth (final) difference synthesis the obvious anisotropic motion of the caesium atom was allowed for by using the fractional atom method[4]. The caesium atom was split into two half atoms along the x direction. The final electron density map, $\rho(x,z)$, is shown in Fig. 1.

Table 1

	x	y	z
Cs_1	0·296	0·750	0·345
Cs_2	0·322	0·750	0·348
Cs (mean)	0·309	0·750	0·347
Mn	0·049	0·250	0·298
O_1	0·060	0·479	0·180
O_2	0·060	0·021	0·180
O_3	0·160	0·250	0·440
O_4	0·387	0·250	0·157

The calculated values of the interatomic distances are

$Mn–O_1$	= 1·63 Å	$O_1–O_2$	= 2·66 Å
$Mn–O_2$	= 1·63 Å	$O_1–O_3$	= 2·66 Å
$Mn–O_3$	= 1·59 Å	$O_1–O_4$	= 3·60 Å
$Mn–O_4$	= 1·67 Å	$O_2–O_3$	= 2·66 Å
Cs–Mn	= 3·93 Å	$O_2–O_4$	= 3·60 Å
Average Mn–O	= 1·63 Å	$O_3–O_4$	= 3·21 Å

The O–Mn–O interatomic angles were as follows:

$\widehat{O_1MnO_2}$	= 109° 10′	$\widehat{O_2MnO_3}$	= 111° 10′
$\widehat{O_1MnO_3}$	= 111° 10′	$\widehat{O_2MnO_4}$	= 100° 56′
$\widehat{O_1MnO_4}$	= 100° 56′	$\widehat{O_3MnO_4}$	= 122° 02′

The space group *Pnma* projects on to (001) as the plane group *pgm*. The map of $\rho(x,y)$ was computed and plotted as for $\rho(x,z)$. Caesium and manganese peaks were found at $y = 1/4$ and confirmed the correctness of the space group chosen, namely, *Pnma*, rather than $Pna2_1$, since the latter projects as *pgg*.

The co-ordinates of the atoms, as shown in the lower left quarter of the (010) projection (Fig. 2), are shown in Table 1. The two half caesium atoms are recorded separately, and the mean caesium position is also given. For convenience the origin was taken at point O.

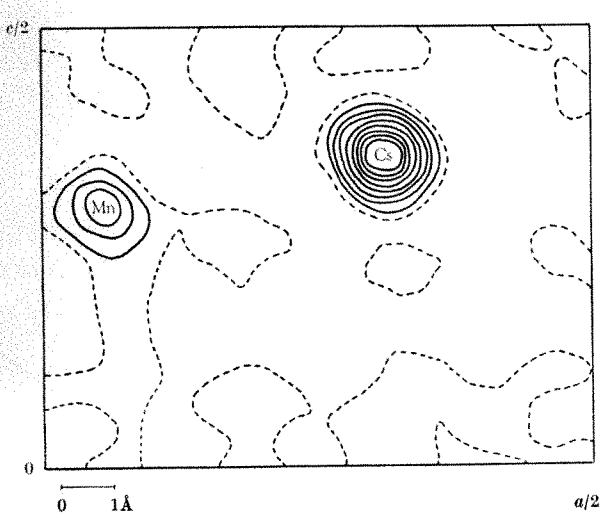

Fig. 1. Final two-dimensional Fourier projection, $\varrho(x,z)$. Contours at equal but arbitrary intervals. Zero contour broken

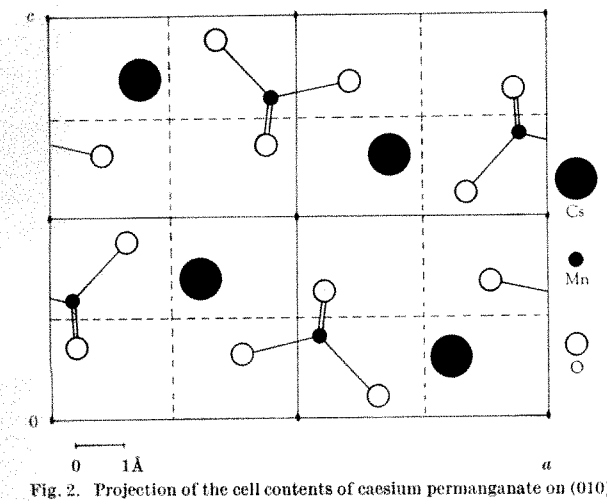

Fig. 2. Projection of the cell contents of caesium permanganate on (010)

The caesium atom is surrounded by eight manganese atoms at a mean distance of 4·38 Å. Four manganese atoms have the same y co-ordinate as the caesium atom, that is, they lie in the same plane. Their distances from the caesium atom are 3·86 Å, 4·58 Å, 4·59 Å and 6·26 Å. The other four manganese atoms lie in planes the y co-ordinates of which differ from the caesium y co-ordinate by $\pm$ 1/4. Their distances from the caesium atom are two at 3·93 Å and two at 3·95 Å. The manganese atom is surrounded by four oxygen atoms at an average distance of 1·63 Å arranged at the corners of a slightly distorted tetrahedron.

We thank the C.S.I.R. (South Africa) for financial assistance during the investigation. We also thank Dr. D. Feil of the Physics Department, University of Cape Town, for assistance in computing.

Interstitial Dislocation Loops in Beryllium Oxide irradiated at High Temperatures

The presence of large numbers of prismatic dislocation loops parallel to the hexagonal {0001} basal planes of beryllium oxide after neutron irradiation at high temperatures (greater than 700° C) has been well established by transmission electron microscopy[1–3]. In addition, relatively low concentrations of loops lying on $\{11\bar{2}0\}$ prism planes have also been observed[3]. However, the nature of the defects comprising these loops has not previously been determined, primarily for two reasons: (*a*) Beryllium oxide does not lend itself to controlled chemical thinning, and specimens have therefore been prepared by crushing or fracture techniques. Prominent $\{10\bar{1}0\}$ cleavage in beryllium oxide causes nearly all chips suitable for study to be cleavage fragments perpendicular to the basal plane, and the abundant basal loops are therefore usually viewed edge-on and appear as lines perpendicular to the *c*-axis. (*b*) Most specimens so far available for investigation have received rather high neutron dosages ($\sim 10^{21}$ *nvt*, $E_n \geqslant 1$ MeV), and have usually contained such high densities of basal loops that overlap prevented the investigation of individual images.

Tilting experiments on chips from two specimens of beryllium oxide irradiated to 3·0 and 5·3 × 10^{20} *nvt* ($E_n \geqslant 1$ MeV) at 1,000° C and one irradiated to 3·5 × 10^{20} *nvt* ($E_n \geqslant 1$ MeV) at 1,200° C have now been carried out to determine the nature of the basal and prism plane loops. These specimens contained low enough basal loop concentrations ($\sim 10^{15}$–10^{16}/cm^3) to allow the investigation of individual loop images. The loops range from about 200 to 2000 Å in diameter, the average size being approximately 1000 Å. Most loops analysed were near the average size. The method of analysis has been described by Edmondson and Williamson[4], and involves large-angle tilting of the specimen to observe the geometrical change in projected loop widths, coupled with observation of the effect on the loop images of a change in sign of the quantity $(\bar{\mathbf{g}}\cdot\bar{\mathbf{b}})s$, where $\bar{\mathbf{g}}$ is the operating diffraction vector, $\bar{\mathbf{b}}$ is the Burgers vector of the dislocation, and s is the deviation from the reflecting position. To determine the Burgers vectors of the two types of loops, diffraction contrast conditions were noted for which the loops were at extinction; that is, $\bar{\mathbf{g}}\cdot\bar{\mathbf{b}} = 0$.

These experiments have established that both the basal and prism plane loops are interstitial in nature, and are both of pure edge character with Burgers vectors perpendicular to their habit planes. Observations of stacking fault contrast within the basal loops for certain $\bar{\mathbf{g}}$ vectors indicate that they are composed of an extra layer inserted into the *C* stacking positions in the normal *ABAB* hexagonal stacking sequence. Such an extra layer is probably composed of beryllium oxide pairs, as Sabine[6] has suggested, and results in a Burgers vector of $c/2 <0001>$. The prism loops are believed to consist of two extra $\{11\bar{2}0\}$ layers, presumably of beryllium oxide pairs, inserted between successive $\{11\bar{2}0\}$ lattice planes, and have Burgers vectors of $a/3 <11\bar{2}0>$.

This analysis represents the first direct identification of the nature of the dislocation loops in neutron-irradiated beryllium oxide, and in particular, the interstitial nature of the abundant basal loops agrees with models of the damage state previously proposed on the basis of X-ray diffraction data[5–7]. A more complete account of this work is being prepared for future publication.

BIOCHEMISTRY

Heat Denaturation of β-Galactosidase: a Possible Approach to the Problem of Catabolite Repression and its Site of Action

Two varieties of enzyme repression have been observed in micro-organisms. In one, addition of the end-product of a biosynthetic pathway to the growth medium specifically prevents synthesis of enzymes concerned with the formation of the product in question. In the other, synthesis of a degradative enzyme is repressed by an end-product (or a closely related metabolite) of the action of the enzyme. Several authors[1,2] have suggested that a repressing metabolite may exert its effect by combining with newly formed ('nascent') enzyme and, thereby, somehow preventing its release from the site of synthesis. Extending this notion, it could be supposed that enzyme formed under non-repressed conditions might still retain 'recognition' sites accessible to a repressing metabolite. Binding of the metabolite to these sites might then be expected to alter certain properties of the enzyme, such as heat stability. It is commonly observed that the heat stability of an enzyme is altered when it is in combination with a substrate or an inhibitor. As an approach to testing for the possible existence of "repression recognition sites", we have examined the effects of metabolites derived from glucose on the heat stability of *Escherichia coli* β-galactosidase. The synthesis of this degradative enzyme, as well as several others, in *E. coli* is repressed when glucose is present during growth and can be similarly affected, though to a lesser extent, by any compound that can be used as a carbon source by the cells[3]. The active repressor is not glucose itself but some compound, as yet unidentified, that is derived from it.

We found that β-galactosidase in cell-free extracts of *E. coli K* 12 became remarkably heat labile in the presence of fructose-1,6-diphosphate (FDP). This could be readily demonstrated either by the usual type of test in which enzymatic activity was assayed at 30° C after heat treatment at some higher temperature, or by determining the time course of enzymatic activity at temperatures of 45° C or more, in the presence and absence of FDP. Partially purified β-galactosidase showed the same response to FDP as the crude preparation, and this is illustrated in Fig. 1. (This effect has been confirmed by Dr. H. V. Rickenberg with crystalline enzyme from both *E. coli K* 12 and *ML* 309.)

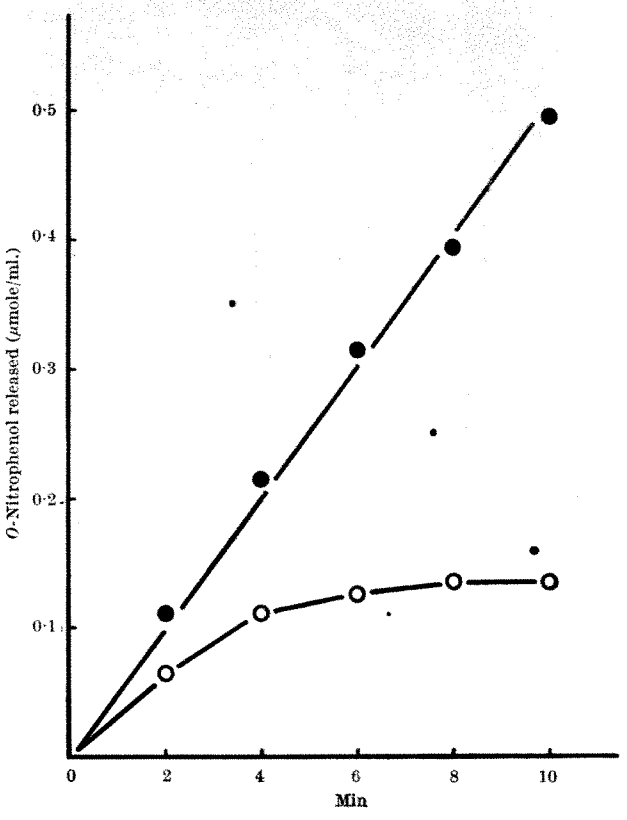

Fig. 1. Effect of fructose-1,6-diphosphate (2·5 mM final concentration) on thermostability of β-galactosidase of *E. coli* at 45° C. The enzyme was prepared from *E. coli K* 12 (grown on lactose) and purified about ten-fold by fractionation with ammonium sulphate. It contained 18 mg protein/ml. and was diluted, as required, with sodium phosphate buffer (0·1 M, *p*H 7·0) to 6 μg/ml. Diluted enzyme (6·0 ml.) at 45° C was added to a solution (12 ml.) at the same temperature containing the substrate (*o*-nitrophenyl-β-D-galactoside, 0·5 mg/ml.) (●), or FDP (○). The mixture was incubated at 45° C and at intervals samples (3·0 ml.) were removed, added to 1·0 M potassium carbonate (2 ml.) to stop the reaction and the extinction of the liberated *o*-nitrophenol measured

In the presence of 2·5 mM FDP and under the other conditions specified for Fig. 1, the enzyme was almost completely inactivated within 3 min at 45° C. It appeared that the effect of FDP was quite specific. Thus, little or no influence on heat stability was observed with lactose, glucose, glucose-1-phosphate, galactose, fructose, fructose-6-phosphate or 3-phosphoglyceric acid. Other compounds that had no effect on heat stability included the following enzyme complexants, methyl-β-D-thiogalactoside, isopropyl-β-D-thiogalactoside, and melibiose. Glucose-6-phosphate, however, was found to increase the heat lability significantly, but not nearly as effectively as FDP. The 'critical' temperature required for observation of the FDP effect is, as anticipated, determined by a number of factors, notably the concentrations of protein and FDP. Control experiments showed that at the usual assay temperatures (30° C) FDP did not measurably affect enzyme activity.

Although *E. coli ML* 308 forms β-galactosidase constitutively (that is, in the absence of inducer), synthesis of the enzyme in this organism is repressed by addition of glucose to the growth medium, as in the wild-type inducible strain[4]. FDP was found to increase the heat lability of the cell-free enzyme from *ML* 308 in the same way.

Of interest, also, is the finding that 10 mM β-mercaptoethanol, which stimulates β-galactosidase activity[5], protects the *K* 12 enzyme against the FDP effect. In this connexion it is noteworthy that replacement of phenylalanine residues in the β-galactosidase of *E. coli* by β-2-thienylalanine leads to pronounced heat lability, and that enzyme modified in this fashion is completely stabilized toward thermal denaturation by a combination of β-mercaptoethanol and Mn^{++} (ref. 6).

These observations do not, of course, prove that FDP is the 'real' repressor through which the glucose effect is exerted, nor do they show that the repressor acts by combination with the nascent enzyme. It is, however, probably significant that β-galactosidase should have a recognition site for FDP, a compound which, in other systems, is a key substance in the regulation of carbohydrate metabolism[7]. Our findings lead to the prediction that two distinct types of mutants possessing resistance to the glucose effect should be obtainable: those damaged in their ability to synthesize fructose diphosphate and those which make altered β-galactosidase molecules which are no longer able to recognize it.

We thank Mrs. S. Brooke for her help. One of us (H. G.) is indebted to the National Science Foundation for a senior postdoctoral fellowship.

Defence by Smear: Supercooling in the Cornicle Wax of Aphids

THE cornicles of aphids, despite their definition in the *Shorter Oxford Dictionary* as the source of honey-dew, in fact secrete a lipid substance, and have a defensive function. Busgen[1] seems to have been the first to have proposed their defensive function, but misconceptions as to their role have persisted. Hottes[2], for example, considered their function to be excretory, and suggested that they released volatile substances derived from the plant sap on which the animals feed. Their defensive function has not been generally recognized; for example, Roth and Eisner[3] neglected them in their review of arthropod defensive mechanisms.

Deflexion of the cornicle or a light touch on the aphid's body elicits the release from the cornicle of a fluid composed of lipid droplets in a water vehicle. The lipid droplets coalesce, and when in contact with a solid surface, rapidly crystallize to form a hard waxy plaque. A small predator, such as a coccinellid, or syrphid larva, or an hymenopteran parasitoid receiving such a droplet is promptly fixed in a cast from which, at least in many instances observed in the laboratory, it is unable to extricate itself. That this unlikely form of defensive mechanism does operate in nature was proven while collecting *Aphis fabae* (Scop.) in the field. Among several thousand aphids examined, two were found with the shrivelled bodies of the hymenopteran parasitoid *Aphidius* sp. fixed to their backs by a plaque of cornicle wax.

The release of cornicle wax is under reflex control. Touching the aphid on one side, or deflecting one cornicle, will elicit the waxing response on that side only. Release is achieved by retraction of the cornicle muscle, a slender fibre which is inserted on a valve-like flap at the top of the cornicle (Fig. 1) and originates on the integument postero-dorsal to the base of the cornicle. Expulsion is evidently effected by abdominal turgor, for there is no contractile structure surrounding the base of the cornicle. Dehydrated aphids cannot be induced to release their cornicle wax. When the cornicle valves are opened, the aphid is in effect releasing material from the haemocoel, the border of the valve is a discontinuity in the integument. It is curious that the nearest parallel among the insects should be the reflex bleeding[4] of the coccinellid—an important predator of aphids.

The cornicle wax arises from cells which may be modified oenocytes. The secretion is stored in large globules enclosed by a membrane, sometimes together with residual cytoplasm and nucleus, sometimes without, which lie in the cornicle stalk and in the haemocoel, below the cornicle (Fig. 2).

The nature of the cornicle wax. The property of the cornicle wax of remaining fluid during the entire life of an undisturbed aphid, and yet of hardening when released by appropriate stimuli, is of some interest, and the following data have been collected on its properties. An aphid may be induced to release its cornicle wax under water. An immersed droplet, retained within a small inverted clean glass cup, will remain as a clear liquid for many hours before crystallizing to form an opaque sphere. On the other hand, contact with a solid surface in air causes rapid crystallization. These observations suggested that the wax may be kept in a liquid state by a solvent which evaporates rapidly in air, but dissolves slowly in water. Octanol, the solvent postulated by Beament[5] as a carrier

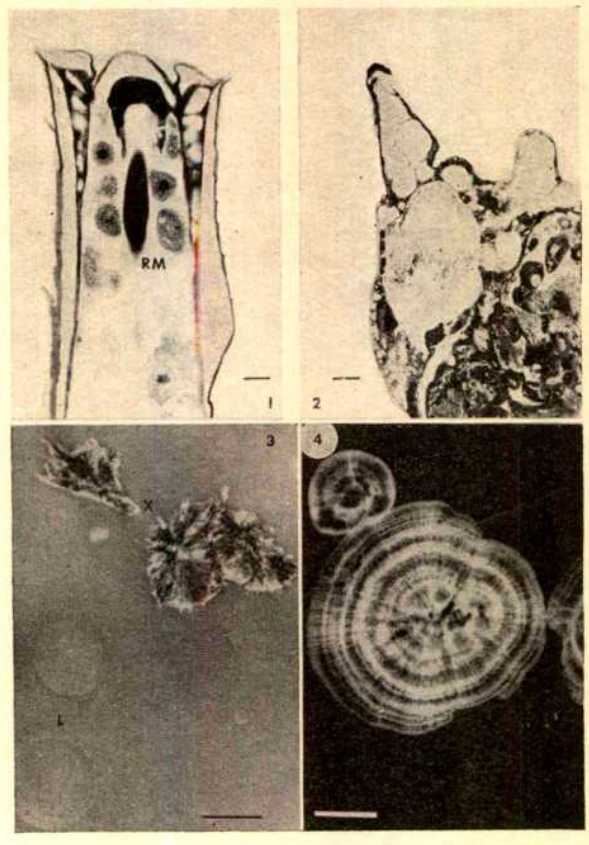

Fig. 1. Longitudinal section of cornicle of *Macrosiphum rudbeckiae* (Fitch.) wall of cornicle, terminal valve, and valve retractor muscle (*RM*). Haemocytes are present in the lumen of the cornicle. Scale, 25μ

Fig. 2. Oblique section through base of cornicle and postero-lateral abdomen. The large open cells in the cornicle and below it contain cornicle wax, part of which has been fixed by osmium and later treated with ethyl gallate. Scale, 100μ

Fig. 3. Cornicle wax of *Macrosiphum rudbeckiae* on surface of glycerol, showing both phases, liquid (*L*) and crystalline (*X*). Direct print from 'Kodachrome' photomicrograph using polarizing microscope. Scale, 1 mm

Fig. 4. Wax plaque on water surface. Plate prepared as in Fig. 3. Scale, 1 mm

of cockroach grease, would fulfil these requirements. However, no solvent of this type was detected by gas chromatography of water samples in which wax had been allowed to crystallize. The liquid state does not depend on an aqueous component, for droplets were maintained on the surface of absolute ethanol and on absolute glycerol for up to 6 h. Droplets of liquid cornicle wax on water and on dehydrating agents remain fluid only under clean conditions and in the absence of vibration.

An alternative explanation of the rapid change of cornicle wax from the liquid to crystalline state is that the fluid is in a stable liquid–crystalline state[6] within the aphid and changes to the solid crystal phase on contact with a seeding nucleus. Certain liquid–crystalline states exhibit birefringence, but no such property was detected in wax droplets on water examined under a polarizing microscope, although birefringence immediately appeared when a crystalline plaque formed (Fig. 3). The persistence of fluid wax droplets on the surface of dehydrating agents also argues against a liquid–crystalline structure involving an aqueous phase.

The rapid crystallization on contact with solid surface, a hair, or dust suggests that the liquid wax is in a supercooled state and that foreign material provides a seeding nucleus for the rapid crystallization. The supercooling property of water is evidently involved in the cold hardiness of insects[7,8], but the aphids appear to be unique in their exploitation of a phase change from the supercooled state.

The melting point of the wax of the golden-rod aphid *Macrosiphum rudbeckiae* (Fitch.) is about 48° C, that of *Myzus persicae* (Sulz.) about 42° C, and of *Aphis fabae* (Scop.) about 37·5° C. The waxes of these three species should therefore crystallize on seeding at normal summer temperatures.

The chemistry of the wax is as yet unknown. Drops of the liquid wax placed on the surface of a 1 per cent osmium tetroxide solution in 0·1 M phosphate buffer, *p*H 7, did not darken until after crystallization, when it gained access to unsaturated bonds. Chibnall *et al.*[9] examined a wax extracted from the aphid *Pemphigus xylostei* and found it to resemble that of the cochineal insect, which is composed of *n*-triacontanoic acid ($C_{30}H_{60}O_2$) and a corresponding keto-acid and keto-alcohol.

I am grateful to Dr. P. A. T. Swoboda, Low Temperature Research Station, Cambridge, for gas chromatographic examination of samples, and to Dr. David S. Barmby, Marcus Hook Research Laboratory, Sun Oil Company, for directing my attention to the supercooled state.

Stabilization of Factor VIII by Glycerol

THE lability of the blood coagulation substance, factor VIII (antihaemophilic globulin, AHG, AHF), has hindered its investigation and has thus led to a search for techniques to stabilize it. Additions of glycerol[1,2], gelatine[3,4], human serum[4], and human serum albumin[4] were all found to stabilize factor VIII activity, but the degree of effectiveness of such additions has not been defined. The investigation reported here was an attempt to evaluate the action of glycerol in quantitative terms.

Factor VIII stability was tested in platelet-poor citrated normal plasma using the 'silicone' technique throughout[5]. All samples were sterile. Factor VIII was assayed by a one-stage procedure[5]. Fresh plasma from the same normal donor was used as standard throughout the investigation.

It was found that glycerol effectively preserves factor VIII activity of refrigerated plasma for at least 8 weeks (Fig. 1). Fig. 2 illustrates the extent to which glycerol protects against loss of factor VIII activity following *p*H changes. With prolonged storage and at extreme *p*H's, the protective effect of 50 per cent glycerol (v/v) was slightly superior to 30 per cent.

Addition of glycerol to aged untreated plasma did not restore factor VIII activity. Glycerol also failed to increase factor VIII activity in haemophilic plasma, either immediately or when assayed after storage of the mixture.

The results indicate that glycerol is effective in stabilizing factor VIII activity in human plasma. Because factor

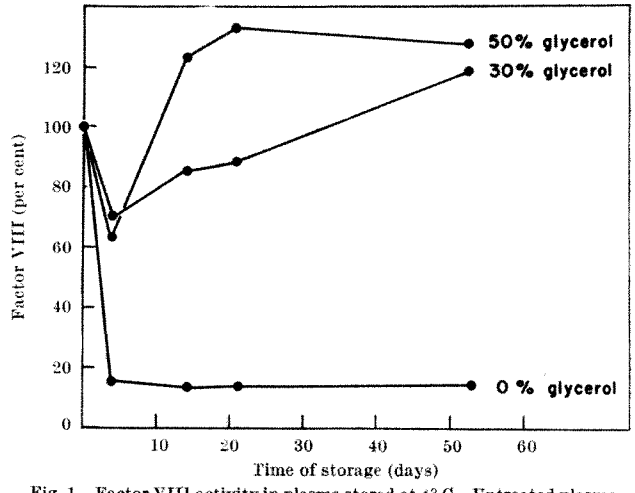

Fig. 1. Factor VIII activity in plasma stored at 4° C. Untreated plasma is compared with the same plasma mixed with glycerol to yield final glycerol concentrations (v/v) of 30 and 50 per cent glycerol. Levels of factor VIII are given as percentages of the original activity of the plasma and correction is made for dilution by glycerol

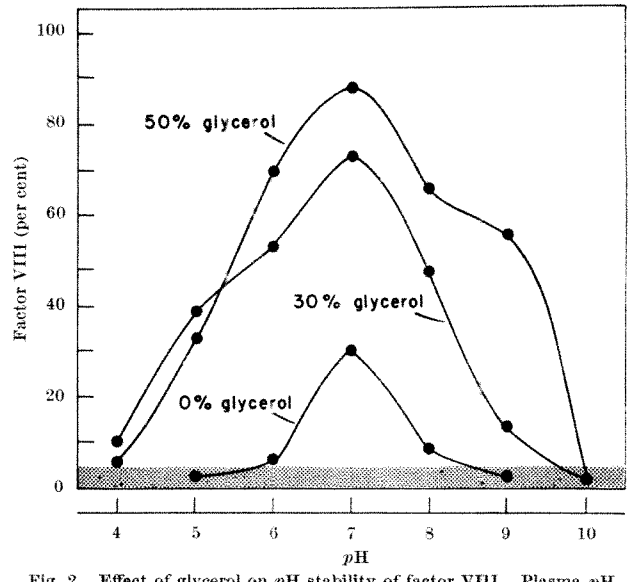

Fig. 2. Effect of glycerol on *p*H stability of factor VIII. Plasma *p*H was adjusted with hydrochloric acid or sodium hydroxide. After storage for 8 days at 4° C, *p*H was readjusted to 7 before assay. The assay method did not permit measurements of factor VIII at levels below 5 per cent. This range is indicated by the shading

VIII is even more labile in purified preparations[2,4], addition of glycerol may facilitate further purification of this coagulation factor as it has done in the case of certain labile enzymes[6].

Dependence of Relative Sweetness on Hydrophobic Bonding

MANY differing types of sweet compounds have been known for some time, but it is only in recent years that an extensive investigation of the subject has been undertaken. Ferguson and his co-workers[1–5] examined the physiological aspects of taste and attempted to correlate relative sweetness with certain physical properties.

We have been able to correlate biological activity in many systems[6] using the following equation:

$$\log BR = -k\pi^2 + k'\pi + k''\sigma + k''' \qquad (1)$$

BR is the biological response which could be applied in this case to RS, the measured relative sweetness, σ is the Hammett constant and π is the hydrophobic bonding constant[7]. π is defined as $\log P_X/P_H$ where P_H is the partition coefficient of the parent compound between octanol and water, and P_X that of a derivative.

The relative sweetnesses of some derivatives of 2-amino-4-nitrobenzene with respect to cane sugar were measured by Blanksma and Hoegen[8] and are shown in Table 1. The following equations were calculated from their data by the method of least squares:

$$\log RS = 1{\cdot}214\pi + 1{\cdot}970 \qquad 0{\cdot}766\,(r)\ 0{\cdot}476\,(s) \quad (2)$$

$$\log RS = 1{\cdot}610\pi - 1{\cdot}831\sigma + 1{\cdot}729 \qquad 0{\cdot}936\,(r)\ 0{\cdot}282\,(s) \quad (3)$$

$$\log RS = 0{\cdot}119\pi^2 + 1{\cdot}485\pi - 1{\cdot}848\sigma + 1{\cdot}742 \qquad 0{\cdot}936\,(r)\ 0{\cdot}308\,(s) \quad (4)$$

r is the multiple correlation coefficient and s is the standard deviation. Equation (2) shows the high dependence of relative sweetness on hydrophobic bonding, and equation (3) confirms the observation of Lawrence and Ferguson that sweetness increases as the basicity of the derivative rises. F tests show that the π term in equation (2) is significant at $> 0{\cdot}975$ and that the addition of the σ term is significant at $> 0{\cdot}99$. Equation (3) accounts for 88 per cent of the variance in the data. Since the correlation is not improved by the addition of a π^2 term in equation (4), we can assume that the π values investigated are relatively low and fall in the "linear" portion of the parabolic curve.

Table 1. RELATIVE SWEETNESS OF 2-AMINO-4-NITROBENZENES (Ref. 8)

Group	σ	π	log RS Obs.	log RS Calc.*	Δlog RS

* log RS was calculated from equation (3).

The substituents methoxy, ethoxy and propoxy are an excellent example of the dependence of relative sweetness on π. It can be seen from Table 1 that their σ values are approximately constant, whereas their π values parallel the increase in sweetness. However, if π is further increased by the addition of CH_2 groups, the compounds will become less soluble in water and eventually tasteless. Kaufmann and Schweitzer[9] report the sweetness of the butoxy derivative as much less than that of the propoxy.

An important prerequisite for sweetness is high anionic character or the ability to form hydrogen bonds with water. Once the compound is in the aqueous phase, its sweetness will then be determined by favourable partitioning on to the receptor sites on the tongue. This step may depend on hydrophobic bonding, degree of polarity, distance of charge separation in the molecule, electron density at a specific point in the molecule as measured by σ, and steric effects.

It can be inferred from equation (3) that the receptor site consists of an area for hydrophobic bonding coupled with a site for electronic bonding.

Sugars are known to be very soluble in water, but are rather low on the relative sweetness scale, so that their attachment to the receptor sites is weak and critically dependent on their stereochemistry. Saccharin is used commercially as the sodium or calcium salt so that it will be readily soluble in water. Its sweetness decreases if the dissociation is inhibited by increasing the concentration in water or by the addition of sodium ions[10]. Any substitution on the isothiazole nucleus which causes loss of solubility also causes loss of sweetness[11]. The benzene ring presumably plays a part in the hydrophobic bonding to the receptor site. The sweetness of the 2-amino-4-nitrobenzenes is very dependent on the position of the substituent and its effect on the electrons of the ring. A distribution of charge occurs when an electron donating group is in a *para* position to the nitro group, as in the derivatives in Table 1, or when an electron attracting group is in a *para* position to the amino group. Examples of this type are the substituents —COOH and —SO_2NH_2 which Ferguson and Childers[5] reported as being sweet. Other sweet compounds such as sucaryl, 5-benzyl-2-furfuraldoxime and dulcin also fall into the general pattern of requiring charge separation for solubility and sufficient hydrophobic bonding power.

Precursor–Product Relationship between Nuclear and Cytoplasmic Ribonucleic Acid

IN a previous communication[1] a simple kinetic model for the incorporation of radioactive adenine into the purine bases of nuclear and cytoplasmic ribonucleic acid (RNA) of exponentially growing cells was proposed. This was used in the evaluation of kinetic data reported by Harris and Watts[2]. Harris[3], in questioning the validity of the model, raised objections based on his interpretation of an equation derived from considerations of our model.

Harris[3] correctly points out that equation (1) of our communication[1] may be written as:

$$\frac{d(^aSc)}{dt} = \gamma\,(^aSn - {}^aSc) \qquad (a)$$

Where ^aSn is the specific activity of adenine in the nuclear RNA, and ^aSc is the specific activity of adenine in the cytoplasmic RNA.

This equation (a) does not state that ^aSc should decrease with $(^aSn - {}^aSc)$ as Harris[3] concluded. It does suggest that a decrease in $(^aSn - {}^aSc)$ should lead to a decrease in $\frac{d(^aSc)}{dt}$. This implies that the rate of change of specific activity of adenine in the cytoplasmic RNA should decrease with time. This is shown more clearly by equation (2) in our earlier communication[1], which represents a saturation type curve with $\frac{d(^aSc)}{dt}$ decreasing with time. Thus, the increase in ^aSc with time as observed experimentally (ref. 2, Fig. 1) is in no way contradictory to equation (a). If it were, the validity of equations (2), (3) and (4) (ref. 1) which are derived from equation (1) should be in question, and they are not.

An "almost linear" increase in ^aSc with time as observed by Harris *et al.*[2] does not raise any serious objection to our hypothesis. It is noticed that for $\alpha t \ll 1$, $(1-e^{-\alpha t})$ is approximately equal to αt and equation (2) in ref. 1 is reduced to a linear relationship, with the slope given by $\gamma\,{}^aSn(0)$. In fact, this suggests a convenient method for the evaluation of γ directly from the slope of the straight line, ^aSc against time. The value of γ, $0{\cdot}34 \times 10^{-3}$/min, estimated by this procedure is comparable to $0{\cdot}43 \times 10^{-3}$/min as obtained by the more rigorous method[1].

Recently, Harris *et al.*[4] reported more data on the incorporation of [8-^{14}C] adenine into RNA fractions of HeLa cells. These investigations differed from earlier ones in having a shorter labelling period (10 min) and in the pattern of incorporation of radioactivity. The following analysis, made at the request of Dr. Harris, shows that the new data are also consistent with the model proposed.

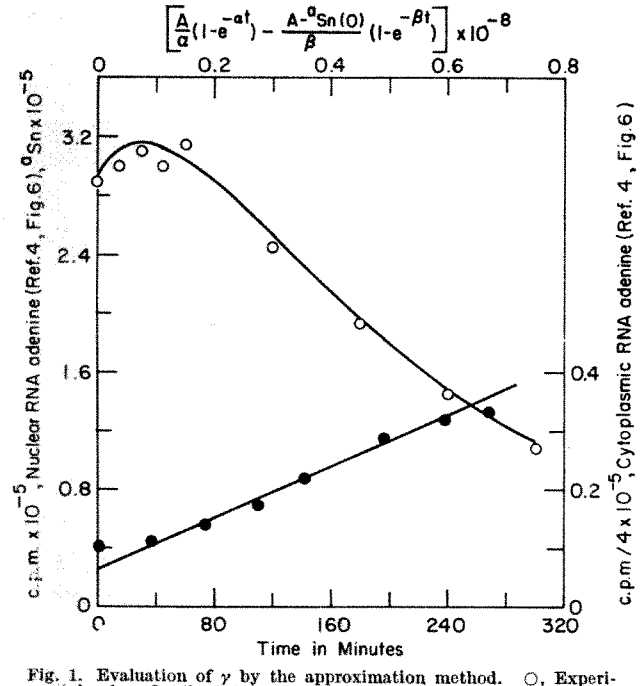

Fig. 1. Evaluation of γ by the approximation method. ○, Experimental values for the total amounts of radioactivity in nuclear RNA adenine reported by Harris *et al.* (ref. 4, Fig. 6). The curve through these points is the theoretical curve calculated from equation (b) for A, $5{\cdot}0 \times 10^5$, $^aSn(0)$, $2{\cdot}9 \times 10^5$, α, $5{\cdot}0 \times 10^{-3}$ min and β, 20×10^{-3} min. ●, Data reported by Harris *et al.* (ref. 4) plotted in accordance with equation (d)

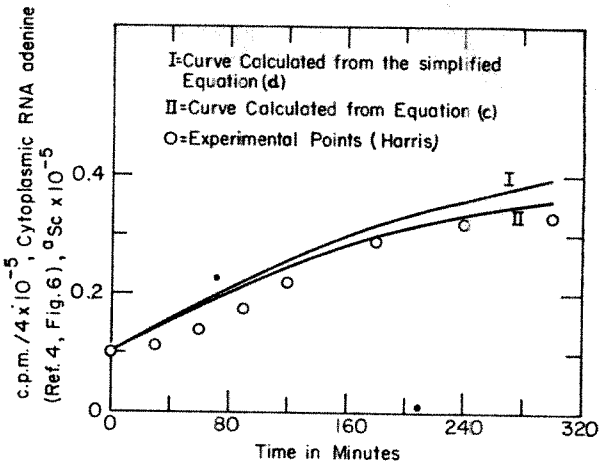

Fig. 2. Comparison between experimental and calculated values for the total amounts of radioactivity in cytoplasmic RNA adenine

In these studies (ref. 4, Fig. 6) the total amounts of radioactivity in purine bases are reported instead of specific activities. In order to maintain a continuity with the earlier treatment we have preferred to use the equations containing terms for specific activity. These expressions can be directly applied to the data reported by Harris *et al.*[4], provided the values for total amounts of radioactivity are multiplied by an appropriate factor so that the ratio of the total amounts of radioactivity in adenine of nuclear and cytoplasmic RNA is equal to the ratio of the corresponding values for specific activity. (After the completion of analysis of these data we have noticed that Fig. 7 in a recent communication by J. W. Watts[5] essentially represents a part of Fig. 6 in ref. 4. A comparison of the two figures indicates certain inconsistencies in the units used by the authors. However, it is gratifying to note that this does not affect our analysis due to a fortunate choice of 'correction factor' used in these calculations. The values in Figs. 1 and 2 ($10^{-5} \times$ c.p.m./μmole) of this communication should be regarded as specific activities.)

The specific activity of adenine (^aSn) in nuclear RNA (total amount of radioactivity, ref. 4, Fig. 6) can be represented by:

$$^aSn = Ae^{-\alpha t} - (A - {}^aSn(0))e^{-\beta t} \qquad (b)$$

where $A = 5{\cdot}0 \times 10^5$, $^aSn(0) = 2{\cdot}9 \times 10^5$, $\alpha = 5{\cdot}0 \times 10^{-3}$/min, and $\beta = 20 \times 10^{-3}$/min as shown in Fig. 1 of this communication. (The time scale in these equations is essentially the same as that used in Fig. 6 of ref. 4. Labelled cells are transferred to non-radioactive medium at '0' time which corresponds to the second point in Fig. 6 of Harris *et al.*[4]). On integration, equation (a) can then be written as:

$$^aSc = \left[{}^aSc(0) + \frac{\gamma A}{\alpha-\gamma} - \frac{\gamma(A - {}^aSn(0))}{\beta-\gamma}\right]e^{-\gamma t} + \frac{\gamma(A-{}^aSn(0))}{\beta-\gamma}e^{-\beta t} - \frac{\gamma A}{\alpha-\gamma}e^{-\alpha t} \qquad (c)$$

for $^aSc = {}^aSc(0)$ when $t = 0$. For a quantitative evaluation of equation (c) we need the value of γ. Since $^aSn \gg {}^aSc$ during the early period of incorporation, we can use the approximation applied earlier[1] to estimate the value of γ. The simplified equation in this case is given by:

$$^aSc = {}^aSc(0) + \gamma\left[\frac{A}{\alpha}(1-e^{-\alpha t}) - \frac{(A - {}^aSn(0))}{\beta}(1-e^{-\beta t})\right] \qquad (d)$$

Since the amount of cytoplasmic RNA obtained by the phenol method has been shown to be four times the amount of nuclear RNA, the quantities estimated from Fig. 6 in

ref. 4 are divided by four. In Fig. 1 one-fourth of the total amount of radioactivity in cytoplasmic RNA (ref. 4, Fig. 6) is plotted in accordance with equation (*d*). γ is estimated to be $0{\cdot}44 \times 10^{-3}$/min from the slope of the straight line in Fig. 1. It may be noted that the value of γ, $0{\cdot}44 \times 10^{-3}$/min, estimated from these data is in excellent agreement with one ($0{\cdot}43 \times 10^{-3}$/min) obtained from the experiments reported earlier by the same authors[1,2]. The deviation of experimental points from the straight line during the early period of incorporation (Fig. 1) is primarily due to the presence of low molecular weight RNA, which is known to undergo rapid turnover[6]. As shown in Fig. 2 the deviation of experimental values from the theoretical values derived from equation (*d*) during the later period of incorporation is partly due to omission of the second term in the right-hand side of equation (*a*).

The behaviour of guanine (ref. 4, Fig. 6) is similar to that observed in our studies and has been discussed in detail elsewhere[6]. Suffice to say that the parabolic nature of the curve for guanine in cytoplasmic RNA can be readily explained on the basis of the saturation type curve obtained for the same base in nuclear RNA.

The discrepancies (emphasized by Harris[3]) in the amounts of radioactivity lost from the nuclear RNA and those gained by the cytoplasmic RNA do not contradict the hypothesis of the nuclear origin of cytoplasmic RNA. It should be noted that equation (*a*) does not indicate the mechanism involved in the transfer of radioactivity from the acid-soluble precursor pool to nuclear RNA, and for that reason it does not exclude the possibility of its degradation. Recent investigations (not yet published) suggest that such degradation is more prominent in non-growing cells. Equation (*a*) is merely an expression for the behaviour of cytoplasmic RNA in relation to that of nuclear RNA acting as an immediate precursor. The general applicability of the analysis over a wide range of variations in the relative distribution of radioactivity in nuclear and cytoplasmic RNA appears to be amply demonstrated by the data reported by Harris *et al.*[1-4] and those obtained in this laboratory[6].

Provitamin A_2: Electroretinographic Measurements of its Effect on Photopic Sensitivity in Chicks

RADIANT energy absorption in chickens normally occurs in the molecules of the vitamin A_1-based rod and cone pigments rhodopsin and iodopsin. The participation of rhodopsin and iodopsin in scotopic and photopic vision, respectively, has been demonstrated by the Purkinje shift, both in behavioural[1] and in electroretinographic experiments[2].

That a displacement of the spectral sensitivity as the result of dietary manipulation is possible is shown by the work of Shantz *et al.*[3], who succeeded in modifying the vitamin A_1-based retinal pigment of rats by feeding vitamin A_2 instead of vitamin A_1. Since the rat retina consists almost exclusively of rods, the vitamin A_2-based pigment porphyropsin takes the place of rhodopsin, which implies a shift in the absorption maximum (λ_{max}) by about 20 mμ toward the red end of the spectrum.

Recently, Budowski *et al.*[4] showed that 3′-hydroxy-3,4-dehydro-β-carotene (anhydrolutein) is converted in the chicken to vitamin A_2. The feeding of this carotenoid as the sole source for vitamin A should, therefore, result in the appearance of porphyropsin and cyanopsin in the chicken retina. Cyanopsin is a vitamin A_2-based cone pigment which has been produced *in vitro*[5], but which has not yet been extracted from retinae. Its absorption maximum is at 620 mμ while that of the vitamin A_1-based cone pigment iodopsin is at 562 mμ. We have tried to demonstrate electroretinographically the effect of anhydrolutein on the photopic sensitivity of the chicken.

One-day-old cockerels (New Hampshire crossed with White Leghorn) were kept on a basal vitamin A-deficient diet (ground sorghum, 65 per cent; solvent-extracted soybean meal, 25 per cent; fish meal, 3 per cent; wheat bran, 4 per cent; vitamins B and minerals, 3 per cent). At the end of 20 days, chicks exhibiting ataxia and loss of appetite were selected. Controls were given the basal diet supplemented with 400 I.U. vitamin A_1 as gelatin beadlets per 100 g feed. The experimental animals were fed the basal diet supplemented with 2 per cent refined soybean oil containing 200 μg anhydrolutein[4] per g oil; they thus received 400 μg anhydrolutein per 100 g feed. The refined soybean oil used was found in previous tests to be devoid of vitamin A activity.

The electroretinographic measurements were carried out on four control and six experimental animals when they were between 13 and 22 weeks old. During this period, the vitamin A_1 storage in the livers of the control chickens amounted to 1,100–1,400 μg per liver. The supply of anhydrolutein, although supporting normal growth, produced only a very small amount of liver storage of vitamin A_2 (20–47 μg per liver). A larger supply would have been desirable, but the amount available was limited.

After an initial ether anaesthesia, necessary for fixing the animal in a head holder and removing the nictitating membrane, only pantocaine was used locally. The tip of a silver-ball electrode, 1 mm in diameter, was applied at the cornea; as indifferent electrode a stainless-steel needle was inserted into the comb. Equal-energy monochromatic flash stimuli (grating monochromator, dispersion ± 3·3 mμ) of 20 msec duration were focused on the pupil of the chicken by an optical arrangement. The electrical responses of the retina (ERG) were recorded by means of a cathode ray oscilloscope through an a.c. amplifier (frequency range between 0·16 c/s and 75 c/s). However, there was not enough energy in the existing light source for superimposing the stimuli on a constant adapting light. This would have been preferable for the determination of the photopic sensitivity. The measurements were, therefore, carried out on dark-adapted chickens after the stimulus strength necessary to elicit a primarily photopic response had been determined. This was done by recording the response to stimuli at 570 and 630 mμ the intensity of which was gradually increased by means of a calibrated neutral density wedge with a range of five log units. Thereafter, the ERG recordings were made. They were elicited by equal energy stimuli over the range from 500 to 700 mμ.

The ERGs obtained were of a complex nature but similar in shape for the two dietary groups. A typical series of ERG recordings obtained from a chicken fed provitamin A_2 is shown in Fig. 1.

The findings of the measurements over the wave-length range tested are presented in Fig. 2. This shows the average photopic spectral curves obtained in the control and the experimental animals. Despite the relatively small amount of anhydrolutein supplied, the spectral sensitivity

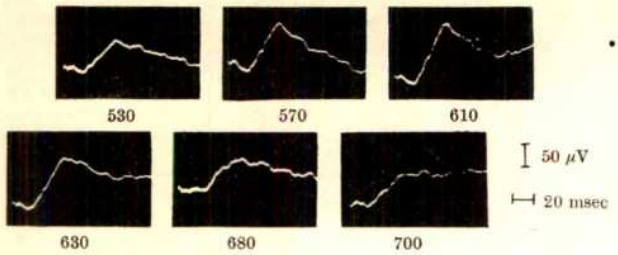

Fig. 1. Typical ERG recordings at different wave-lengths obtained from an animal fed provitamin A_2

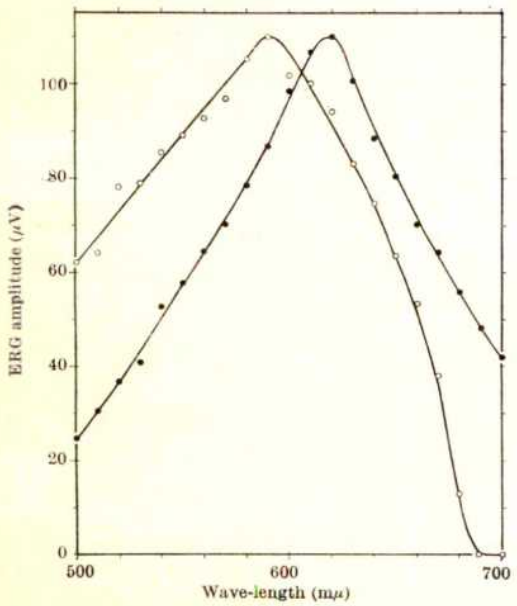

Fig. 2. Photopic sensitivity curves. Open circles: vitamin A_1-fed controls (average of four animals). Filled circles: provitamin A_2-fed chickens (average of six animals)

of the experimental animals shows a distinct shift toward the red as compared to the controls. The difference in photopic sensitivity becomes particularly striking at the red end of the spectrum: at 690 mμ there is practically no measurable response in the controls while a fairly large ERG can still be recorded at 700 mμ in the experimental animals (Fig. 1).

The spectral sensitivity peak at 620 mμ obtained in the experimental animals agrees well with the λ_{max} of cyanopsin[5]. On the other hand, the photopic sensitivity peak at 590 mμ in the controls differs from the λ_{max} at 562 mμ found for iodopsin by Wald *et al.*[6], and from the ERG measurements of Armington and Thiede[2], which have a maximum at around 570 mμ. It agrees, however, with the results from behavioural tests in chickens reported by Honigmann[1].

The most likely explanation for the shift in photopic sensitivity is the substitution of the retinene$_1$ moiety of iodopsin by retinene$_2$, resulting in a cyanopsin-like receptor pigment. The actual nature of the visual pigments obtained under these conditions remains, however, to be established.

The possibility of altering the visual system by dietary means, as evidenced by the modification of the receptor pigment in rats[3] or by the shift in photopic sensitivity in chickens described here, contrasts with the idea[7] that the pattern of visual systems is determined genetically, rather than by environment.

We thank Miss Jeana Gros for the anhydrolutein preparation. This work was supported in part by the U.S. Department of Agriculture.

Liver Transplantation Effects on Canine Plasma Lipids

IN order to achieve long-term success of the hepatic homograft, satisfactory metabolic function of that organ in the host is essential. Since the liver is directly and/or indirectly involved in the synthesis and metabolism of the lipid fractions, it is important to know the effect of transplantation on the host's 'lipid profile'.

Orthotopic hepatic homografts were performed on a series of thirteen healthy dogs, of which three survived more 100 days[1,2]. The data used in this communication were obtained from these three dogs. Azathioprine ('Imuran', an immunosuppressant), methionine and antibiotics were administered daily post-operatively. The diet consisted of commercial dog food fed *ad libitum*. Fasting, peripheral venous bloods were collected pre- and post-operatively twice a week for clinical and lipid analysis.

All three dogs had some evidence of early liver injury as judged by changes in standard liver-function tests. There were, in each, rises in alkaline phosphatase, SGOT and SGPT. Only one of the three animals developed hyperbilirubinaemia. The changes in these dogs, as well as a much larger series of animals, have been reported in

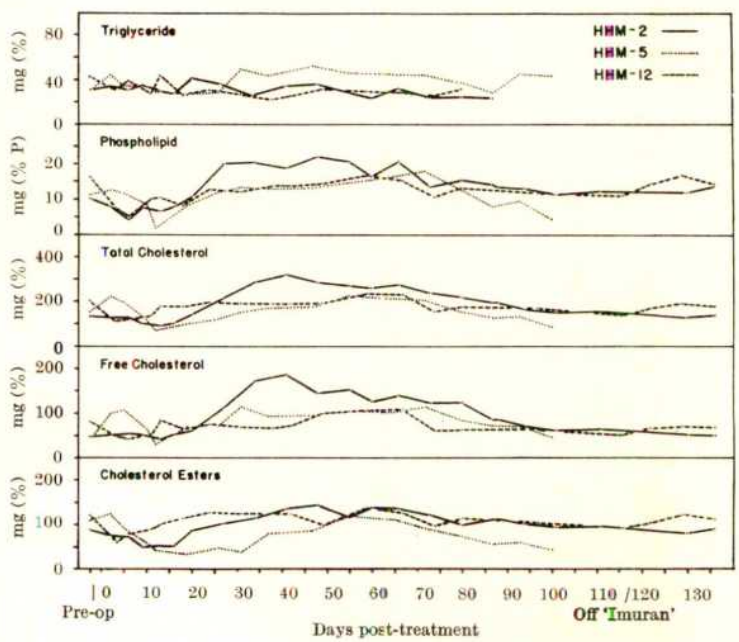

Fig. 1. Plasma 'lipid profile' in the canine hepatic homograft

detail[2]. The dog which became jaundiced during the period of the present investigation died after 100 days. The other two were still alive with good liver function 285 and 295 days post-transplant.

The 'lipid profile', consisting of total, free and esterified (by difference) cholesterol, phospholipid, non-esterified fatty acid (NEFA), and triglycerides (Fig. 1), was analysed by standard chemical procedures[3–6]. Of the lipid classes, cholesterol and phospholipid fractions changed the most. Total cholesterol dropped to about 50 per cent of the pre-operation value in the first ten days post-operative and returned to the pre-operation value in thirty to forty days. Esterified cholesterol also dropped to about 50 per cent of the pre-operation level and returned to the pre-operation value within forty to fifty days post-operative. Here again, we saw the adverse effects on the liver enzyme system, as demonstrated in the liver-function tests. Phospholipid dropped by the tenth day post-operation to about 50 per cent of pre-operation value, then returned to the pre-operation value or above by the thirtieth day. Triglyceride did not change much, remaining in the 30–40 mg per cent range. The NEFA values fluctuated between 430 and 1,800 μequiv./l., exhibiting no obvious trends.

The phospholipids were further analysed to ascertain whether one particular phosphatide was responsible for the change within the first thirty days. After extracting the total lipid[7], separation by thin-layer chromatography[8] yielded four phosphorus-containing fractions. These fractions were tentatively identified as lecithins, sphingomyelin, lysolecithin and phosphatidylethanolamine. Phosphorus determinations were performed[4] on these four fractions. The four samples analysed were from the fifth, tenth, twentieth and thirtieth days post-operation. The results indicated a uniform change of all four phosphatide fractions even though there was a three-fold change in the total phospholipid.

Azathioprine is known to be a hepatotoxic agent[2]. To be sure that the lipid changes that took place were not caused by the medication, a control series of dogs were administered the same medication ('Imuran', methionine, antibiotics), diet, and care as the experimental dogs, but no surgical operation was performed. Transient rises occurred in SGOT, SGPT and alkaline phosphatase but without the development of jaundice. In these control dogs, the plasma lipids remained unchanged (Fig. 2), indicating that the altered lipid pattern seen in the experimental dogs is not the result of 'immunosuppressant therapy' but is a physiological adjustment by the host to the hepatic homograft or the operational shock.

In the canine hepatic homograft host, acceptable plasma lipid metabolism was obtained after 30–50 days. To properly evaluate these data, we must keep in mind that the peripheral plasma values are an expression of extra- as well as intra-hepatic function, and differentiation between mobilized, synthesized and ingested lipids in the lipid pool is difficult. Extra-hepatic synthesis can compensate for differences to a point, but a liver must be present with reasonably normal function to have a proper 'lipid profile' since the majority of lipid metabolism either takes place in or is controlled by the liver.

This work was aided by grants from the U.S. Public Health Service. We thank Dr. T. E. Starzl and Dr. T. L. Marchioro for their co-operation and support.

Comparison of Physicochemical Properties of Mitochondrial and Nuclear Deoxyribonucleic Acid from Rat Liver Cells

THE discovery of deoxyribonucleic acid (DNA) in mitochondria[1–9] has opened the way for investigations of the long-standing problem of extra-genome cytogenetic determinants. DNA fibres have been found in mitochondria from tissues belonging to various different classes of animals[1]. The principal difficulty to be dealt with in the isolation of mitochondrial DNA is caused by the necessity of separating the soluble nuclear DNA, adsorbed on the surface of mitochondria. For this purpose we used a method of purification of mitochondria in 'Urographin' density gradient[8] or treatment of the mitochondrial fraction with DNase (150 μg/ml. for 1·5 h at 0° C). Fibres of high-polymer deproteinized DNA were obtained by means of the phenol method after Kirby[10] and Marmur[11]. The average DNA content in liver mitochondria amounted to 0·65 μg/mg protein.

In an attempt to determine how far mitochondrial DNA is identical with nuclear DNA from rat liver cells, both these nucleic acids were submitted to physico-chemical analysis. Comparison of the hydrodynamic properties of mitochondrial and nuclear DNA and of their modification on exposure to DNase has shown that both the DNAs display high viscosity, although their response to addition of DNase proved to be different. While, as early as 4 min after addition of the enzyme, nuclear DNA was found to have lost 40 per cent of its viscosity, the same effect was only attained after 60 min in the case of mitochondrial DNA. The mitochondrial DNA sedimentation constant obtained by centrifugation in ultra-violet light has also

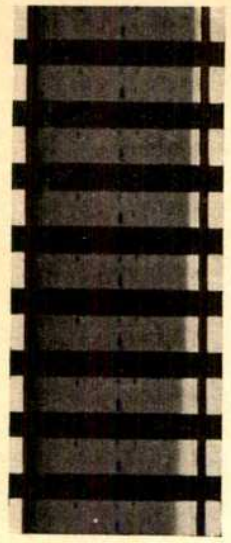

Fig. 1. Determination of sedimentation constant of mitochondrial DNA, using ultracentrifugation in ultra-violet light. Velocity, 30,000 r.p.m.; time, 30 min; DNA concentration, 30 μg/ml. in 0·15 M sodium chloride

shown the high-polymer structure of this nucleic acid and its distinction from nuclear DNA. Thus, the sedimentation constant of mitochondrial DNA, purified on a 'Sephadex *G*-75' column in 0·15 M sodium chloride, was $18{\cdot}6 \times 10^{-13}$ sec, giving a molecular weight of $4{\cdot}8 \times 10^6$ (Fig. 1), while in the case of nuclear DNA, the S_{20} amounted to $22{\cdot}2 \times 10^{-13}$ sec, or to a molecular weight of 8×10^6.

Differences between properties of mitochondrial and nuclear DNA were also shown by determinations of the hypochromic effect, which was found to amount to 38 per cent for mitochondrial DNA and to 53 per cent for nuclear DNA. The transition temperature of the DNA helix for mitochondrial DNA was found to be within a higher range, indicating the prevalence of guanidine–cytosine pair couple bases.

The descending paper chromatogram method[12] was used for establishing the composition of mitochondrial DNA and for its comparison with that of nuclear DNA. Analysis of the spots revealed the composition of nitrogen bases shown in Table 1. This showed the presence of a minor component of DNA 5-methylcytosine.

Table 1. BASE COMPOSITION OF MITOCHONDRIAL AND NUCLEAR DNA

(Mol. per cent)

	G	*A*	*C*	*T*	*G*+*A*/*C*+*T*
Mitochondrial DNA	31	21	24	24	1·08
Nuclear DNA	25	26	21	28	1·04

Rabinowitz *et al.*[13] obtained somewhat different values for the guanidine–cytosine content of nuclear and mitochondrial DNA from chick embryos. Our experiments were made on adult rats, which may explain this difference. Nevertheless, further investigations with larger quantities of mitochondrial DNA are necessary for this question.

One of the properties peculiar to mitochondrial DNA is its capacity to undergo structural modification on exposure to ultra-violet light. The mechanism of ultra-violet irradiation injury has been shown to depend on the formation of thymine dimers between two thymine molecules in a single DNA chain[14]. This results in a loss of the replication capacity of DNA and in arrest of its synthesis. It appeared to be of interest to establish whether such a mechanism actually occurs on irradiation of mitochondrial DNA, that is to find whether in this case errors in structure of the DNA molecule were really due to the formation of thymine dimers. To this end, DNA preparations from liver cell mitochondria and nuclei were exposed to ultra-violet irradiation at 2537 Å, total dose 960 ergs/mm² ('*BUV*-30', ultra-violet output 95 per cent). After DNA hydrolysis, the composition of nitrogen bases was studied. The chromatogram revealed the appearance of new spots with R_F 0·83, conforming to the R_F of dimerized thymine. Non-irradiated thymine is known to have an R_F of 0·72. The percentage of thymine dimers (compared with total thymine) amounted to 16 per cent for mitochondrial DNA and to 25 per cent for nuclear DNA.

The possibility of extra-chromosomal determinants of heredity in mitochondria raises the problem of their partial genetic autonomy. Calculation of the possible information content inherent to the DNA in a single rat liver mitochondrion gives a value equivalent to 120 proteins with a molecular weight of 20,000. The amount of DNA present in mitochondria is thus sufficient for the reproduction of mitochondrial protein structure.

Mitochondrial DNA may be assumed to contain information for synthesizing proteins of the electron transport chain and coupled phosphorylation and, consequently, for determining one of the universal mechanisms of energy generation, inherent to all cells, irrespective of their specialization. On the other hand, nuclear DNA may be responsible for controlling the rate of protein synthesis, thus determining the specificity of the cell. Such a hypothesis is supported by evidence from the use of the method of radiation inactivation of nuclei[15], which shows the respiratory function of mitochondria to be independent of the nucleus, the latter being responsible for only activation of respiration. The possibility of a genetic system located in mitochondria does not invalidate the existence of genetic control from the nucleus.

To sum up, investigation of a mitochondrial DNA preparation in an open system in the presence of RNA-polymerase (made by Dr. Markosian and Dr. Shmerling) has shown that RNA synthesis occurs.

Prediction of the Relative Passive-transfer Rates of Short-chain Fatty Acids across Lipid Membranes

A VAST quantity of literature has accumulated concerning the mechanism of lipid transfer across the intestinal wall, yet the process still remains largely unclear[1]. One point which seems definitely established is the difference between the transfer of short-chain fatty acids, which appear free in the liver portal blood, and the long-chain acids ($> C_{10}$), which appear mainly in lymph in the form of triglycerides[2]. Whereas the latter transfer system is complex, involving emulsification, micelle formation and

enzymatic esterification, the former may be relatively simple, involving a combination of a fatty acid permease and passive penetration. Smyth[3] and Barry and Smyth[4] have demonstrated that fatty acids containing from two to six carbons are actively transported from the mucosal to the serosal side of intestinal sacs *in vitro*. Higher concentrations of fatty acids suppress *in vitro* active transport, the suppression being more pronounced with increasing chain length, but this inhibition does not seem to influence the rate of disappearance of fatty acids from inside the intestine *in vivo*[4]. The possible contribution of passive transport is therefore of some interest.

Carr[5] has proposed that the decreasing capacity of fatty acids to be absorbed at higher chain lengths might be explained on the basis of molecular size and has shown[6] that the permeation of a fatty acid salt through artificial porous membranes decreases sharply when its concentration is increased above the critical micelle concentration. Since critical micelle concentration in turn decreases with increasing chain length, it is reasonable to assume that some selectivity would be obtained by means of penetration through aqueous pores. Micelle formation would be limited with the smaller fatty acids, however, and passive penetration would therefore be determined either by diffusion through aqueous channels or by transfer across lipid membranes.

The observed *in vivo* rate of absorption at 38° C increases only about 20 per cent as the chain length is increased from two to six carbon atoms[4]. On the basis of the benzene : water partition coefficient alone, the passive penetration rate through lipid membranes should increase nearly 300-fold with a change from two to six carbon atoms (see Table 1), which would imply that passive transfer through lipid is a minor contributing factor below C_6. This would suggest either that active transfer tends to increase with decreasing chain length to compensate or that passive transfer by aqueous pathways is a major factor. However, it is also possible that passive transport across lipid membranes may be much more prominent for the lower fatty acids than would be expected from the simple oil : water partition coefficients.

Table 1. COMPARISON OF RELATIVE RATES OF FATTY ACID TRANSFER: OBSERVED TOTAL RATES AND THEORETICAL PASSIVE RATES ACROSS LIPID MEMBRANES

Acid	No. of carbon atoms	*In vivo* absorption rate	log *P*	log *C*	*pK*	Passive rate (R/R_A)
Acetic	2	1·00	+1·49	−1·26	4·75	1·00
Propionic	3	1·09	+0·95	−0 55	4·87	1·20
Butyric	4	1·09	+0·37	+0·03	4 81	0·80
Valeric	5	1·17	−0·12	+0·57	4·82	0 68
Caproic	6	1·22	−0·85	+1·21	4·83	0·46
Refs.		(4)	(8)	(10)	(9)	

P = Vapour pressure of pure acid in mm of mercury at 38° C; C, benzene: water partition coefficient, R/R_A, $P^{0.6}C^{0.4}K_A/P_A{}^{0.6}C_A{}^{0.4}K$, where subscript A indicates values for acetic acid. The *in vivo* absorption rate from rat intestine was reported for 20 mM acid over a 20-min period at 38° C and *p*H 7·4.

The hypothesis has recently been advanced[7] that the vapour pressure of the solute may be an important factor in the rate of penetration of biological membranes. For similar organic solutes, the permeability constant is nearly proportional to $P\gamma C^{(1-\gamma)}$, where P is the vapour pressure of the pure solute at a given temperature, C is the oil : water partition coefficient, and γ is a number between 0 and 1·0 which is related (in this hypothesis) to the extent of dissociation of solute from both lipid and aqueous phases during passage into the membrane. γ was found empirically to be near 0·60 for alcohol and ester penetration into a variety of animal cells. In order to apply this relationship to fatty acid penetration, the following assumptions will be made: (*a*) Passive transfer through a lipid membrane involves the passage of un-ionized fatty acid. At *p*H 7·4, as used by Barry and Smyth[4], about 0·2 per cent of the fatty acid will be un-ionized, and the amount of un-ionized acid can be approximated as $m[H^+]/K$, where m is the total concentration of acid and its salt and K is the acid dissociation constant. Since m and $[H^+]$ are held constant, the quantity of un-ionized acid will be inversely proportional to K. (*b*) The value of γ for the un-ionized acid will be the same as for alcohols and esters, or 0·60.

The relative rate of passive transfer will then be proportional to $(P^{0.6}C^{0.4}/K)$ or, in logarithmic form:

$$\log R = 0{\cdot}60 \log P + 0{\cdot}40 \log C + pK + \text{constant},$$

where R is the rate of passage. The values for log P, log C, and pK are given in Table 1 along with the calculated value of R/R_A, or the rate for a given acid divided by the rate for acetic acid (R_A). It may be seen that the passive-transfer rate through a lipid membrane could actually decrease with increasing chain length. On this basis, it would be difficult to distinguish between aqueous and lipid pathways. In either case, active transfer would increase with increasing chain length.

It should be emphasized that both the observed *in vivo* absorption rate and the calculated passive rate are given relative to acetic acid and not relative to each other. Further elaboration on this prediction must await more information about the magnitude of the passive-transport contribution to total transport, the extent of transport through aqueous pores, and the value of γ for fatty acids.

Purification and Chemical Constitution of the Phospholipids from *Corynebacterium diphtheriae* P.W.8

PREVIOUS investigations on the ether-soluble lipids from *Corynebacterium diphtheriae* have revealed the presence of saturated and unsaturated fatty acids with 16 and 32 carbon atoms[1–3].

The fraction extracted with ethyl ether and precipitated by acetone consists mainly of complex lipids[4–6]. Working with this fraction, Asselineau[6] obtained, after column chromatography on silicic acid, a fraction with the following analytical characteristics: melting point 185° C $\alpha_D^{20\,\circ} = +20°$; phosphorus, 3·0 per cent; nitrogen, 0·8 per cent. On acid hydrolysis he obtained an ether-soluble and a water-soluble fraction. The ether-soluble fraction contained palmitic acid and corynomycolic acid; and in the water-soluble fraction he detected inositol, mannose and glycerol.

From an acetone-insoluble lipid fraction we purified a glycolipid which we showed to contain corynomycolic and corynomycolenic acid[7] esterified to trehalose. Further purification of the acetone-insoluble lipids yielded three phosphoglycolipids. The present communication describes the purification, analyses and chemical characterization of these substances.

Isolation of the phospholipids. The fraction of *C. diphtheriae* P.W.8 lipids insoluble in boiling acetone[5] was used as the starting material in this work. This fraction was dissolved in chloroform and passed through a column of cellulose powder (Whatman No. 1). After evaporation of the eluate to 1/10 its volume an equal volume of methanol was added. The precipitate that formed was centrifuged and dried in a desiccator under vacuum.

The dried material was redissolved in a small volume of chloroform and chromatographed on a column of silicic acid (Mallinckrodt) using increasing concentrations of methanol in chloroform: 1/19, 1·5/8·5 and 1/1. The phospholipids were eluted with chloroform–methanol 1/1. After removal of the solvent this fraction was rechromatographed on silicic acid. The following concentrations of methanol in chloroform were used: 2·5/7·5, 3·5/6·5 and 1/1. Three peaks were obtained that we called, respectively, *F* 25, *F* 35 and *F* 50 in accordance with the percentage of methanol used. The homogeneity of the peaks was confirmed by thin-layer chromatography on silicic acid[8]. The results are shown in Table 1. The analytical characteristics of the three fractions are presented in Table 2.

Table 1. THIN-LAYER CHROMATOGRAPHY ON SILICIC ACID OF THE PURIFIED PHOSPHOLIPIDS*

Solvent systems	R_F Fraction 25	R_F Fraction 35	R_F Fraction 50
Chloroform–methanol–water (65 : 25 : 4)	0·46	0·36	0·31
Chloroform–methanol (4 : 1)	0 35	0·31	0·29
Chloroform–methanol–ammonia (80 : 20 : 0·8)	0 28	0·42	0·15
Diisobutylketone–acetic acid–water (40 : 20 : 5)	0·14	0·21	0·07

* The spots were detected by ammonium molybdate-perchloric acid reagent for phosphorus and an alcoholic solution of rhodamine *B* for lipids.

Table 2. ANALYTICAL CHARACTERISTICS OF THE PURIFIED PHOSPHOLIPIDS

	$a_D^{\lambda°}$ C (c = 0·7 in $CHCl_3$)	Melting point	Phosphorus (per cent)	Reducing sugar (per cent)*	Nitrogen (per cent)
F 25	+26°	195–202° C	2·5	10·4	—
F 35	+20°	214–217° C	2·0	7·8	—
F 50	+25°	240–246° C	2·0	13·8	—

* Measured as mannose.

Characterization of the carbohydrates. The three phospholipid fractions were saponified separately by exposure to 15 per cent methanolic potassium hydroxide solution for 45 h at room temperature. After acidification with acetic acid, we recovered 54 per cent, 48 per cent and 41 per cent of *F* 25, *F* 35 and *F* 50, respectively, as ether-soluble fatty acids. The aqueous fractions were desalted by passage through an Amberlite *MB*3 column and evaporated under vacuum, and found to consist of 26 per cent, 20 per cent and 32 per cent of neutral constituents. The hexose content of the latter fractions was estimated with anthrone and was found to be 60 per cent, 58·5 per cent and 71 per cent, respectively. The neutral residue was hydrolysed for a further 8 h with 5 per cent sulphuric acid in a boiling water bath and neutralized by passage through a column of 'Amberlite *IR* 4*B*'. Paper chromatography of the three hydrolysates was carried out on Whatman No. 1 with the following solvent systems: isopropanol–acetic acid–water (6 : 3 : 1); *n*-butanol–acetic acid–water (120 : 30 : 50) and *n*-propanol–ethyl acetate–water (7 : 1 : 2). Glycerol, mannose and inositol were detected in the three hydrolysates by the use of periodic acid–benzidine reagent. The presence of mannose was confirmed by the preparation of the phenylhydrazone (melting point 195°C). There was no depression of the melting point on mixture with authentic phenylhydrazone of mannose. Inositol was further confirmed by preparation of the hexa-acetate with acetic anhydride in pyridine. The crystalline compound has a melting point of 223°–225° C. The mixture with authentic hexa-acetyl inositol gave no depression on the melting point.

Characterization of the fatty acids. The ether-soluble fatty acids from the saponification were obtained as a crystalline product with an average molecular weight of 240 by titration, and a melting point of 44°–55° C. By paper chromatography on Whatman No. 1 paper saturated with 'Nujol'[9] and developed with acetic acid–water (9 : 1) at 45° C for 20 h (descending), two spots were detected by spraying with mercuric acetate and diphenyl carbazide, corresponding to myristic and palmitic acid. They were further characterized by thin-layer chromatography on silica gel *G* (Merck) impregnated with 'Nujol'[10] in the following solvent systems: acetic acid–acetonitrile (1 : 1) and hexane–acetic acid–ethyl ether (83 : 1 : 16) and detected by spraying with an alcoholic solution of rhodamine *B*.

In conclusion, our results confirm those of Asselineau[6] in regard to the non-saponifiable fraction of the phospholipids but differ in regard to the analytical data and the constitution of the fatty acids.

The chemical constitution of these phospholipids of *C. diphtheriae* is similar in many respects to the glycerophosphoinosito mannoside compounds of *M. tuberculosis*, studied by Vilkas and Lederer[11], which was shown to contain palmitic and stearic acid as the fatty acid moieties.

This work was supported by the Fundacao de Amparo a Pesquisa do Estado de S. Paulo (Brazil). We thank the Instituto Pinheiros for furnishing the bacteria, and Prof. Isaias Raw for laboratory facilities.

Effect of Urethan on Nucleic Acids

BIOCHEMICAL investigations have not so far been successful in elucidating the mechanism of action of urethan carcinogenesis. The problem has been studied extensively from a biological standpoint and there are excellent reviews on the subject. Boyland *et al.*[1] and Kaye[2] have investigated its metabolism thoroughly, but its mode of action in the organism is still not understood. The present communication reports preliminary observations on the effect of injected urethan on the nucleic acid metabolism of mice.

Two inbred strains of mice, Swiss and *L*(*P*), were used for experimental purposes. Swiss strain mice are resistant to spontaneous and induced breast carcinomata, while *L*(*P*) strain mice are resistant to spontaneous breast cancer but highly susceptible to chemically induced breast cancer[3]. Swiss strain mice are reported to be susceptible to induced lung and skin cancers, but a carcinogenic effect of urethan on *L*(*P*) mice has not yet been reported. Therefore *L*(*P*) strain mice were used to see if urethan exerted any strain-specific effect.

The following experimental groups were used for investigation.

(1) 10–12-week-old male mice of both strains were injected with 1 mg/g body weight of urethan intraperitoneally and were killed 4 h later.

(2) 10–12-week-old normal males of Swiss and *L*(*P*) strain were injected with 1 mg/g urethan daily for 4 days and were killed 96 h after the first injection.

(3) Swiss males bearing transplanted fibrosarcomata were injected with 1 mg/g urethan intraperitoneally on

the sixth day of transplantation. These were then divided into two groups.

(*a*) Killed 4 h after a single injection of urethan.

(*b*) Injected daily for 4 days and killed 96 h after the first injection.

Animals were killed by decapitation and lung, liver and kidney tissues were used for estimation of RNA and DNA. RNA was estimated by Rosen and Ogur's method[4]. DNA was estimated by Indole's method[5]. Protein was estimated by Folin's method[6]. The content of both the nucleic acids is expressed per μg protein.

Fig. 1 shows the effect of urethan injection on the RNA and DNA content of liver, kidney and lung tissues of normal males (10–12 weeks old) of Swiss and *L(P)* strains. It can be seen at a glance that a single injection of urethan affects the levels of both the nucleic acids of all the three tissues of normal Swiss males. The decrease in the nucleic acid level was 75–80 per cent. Repeated injections of urethan have not caused further decrease in nucleic acid levels. In contrast to Swiss mice, *L(P)* strain mice have not shown any change at all in both the nucleic acid levels even after repeated injections of urethan.

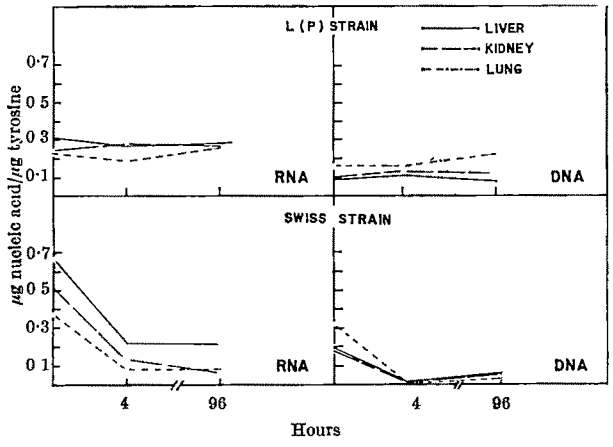

Fig 1. Effect of urethan injection (intraperitoneal) on the nucleic acid content of different tissues of two strains of mice

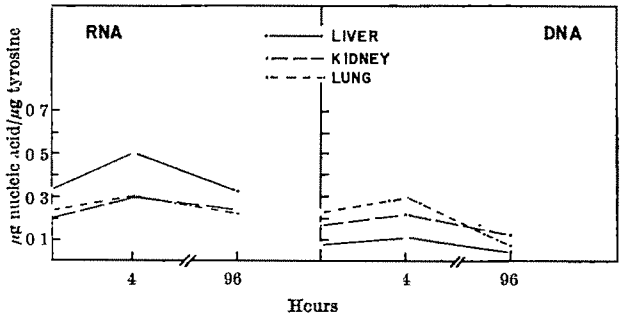

Fig. 2. Effect of urethan injection (intraperitoneal) on Swiss mice bearing fibrosarcomata

Fig. 2 shows the effect of a single injection as well as of repeated injections of urethan on different tissues of Swiss mice bearing fibrosarcomata.

It can be seen that there is an increase in both the nucleic acid levels of all the tissues in the 4-h group. However, in the group receiving repeated injections, there is no significant difference between the treated and untreated animals.

A 75–80 per cent decrease observed in the nucleic acid levels of all the tissues of Swiss mice within 4 h of single injection of urethan is a significant observation. A possible effect of urethan on nucleic acid metabolism was suggested first by Rogers[7] and then by Elion *et al.*[8]. These authors were able to inhibit tumour formation by giving nucleic acid hydrolysates or by thymine but not by uracil. They postulated that urethan inhibits DNA synthesis at the site of thymine biosynthesis. In the present experiments, the inhibitory effect of urethan on RNA and DNA levels is comparable. It may be mentioned here that the effect of urethan on RNA has not been reported previously. The decrease in nucleic acid contents of the tissues of urethan-treated normal Swiss mice is still more significant, as no changes are seen in urethan-treated *L(P)* mice. It has been proved that urethan causes lung adenomata and skin tumours[9] in Swiss mice and thus even its immediate biochemical effects seem to be strain specific.

It is also interesting to observe that the mode of action of urethan in normal Swiss mice is different from that in tumour-bearing mice. It may be stated here that urethan is known as a carcinogenic as well as a carcinostatic compound[9] and it may thus have different modes of action in normal and tumour-bearing mice. These observations, however, are of a preliminary nature and it is essential to study the mechanism of action of urethan in further detail before formulating its role in carcinogenesis. Investigations on these lines are in progress and will be reported later.

Effect of Cortisol on the Synthesis of Chondroitin Sulphate by Embryonic Cartilage

CORTISOL, in low concentrations, profoundly affects the growth of the cartilaginous limb-bone rudiments from embryonic chicks, cultivated in a synthetic medium[1–4]. One aspect of this effect is a decrease in the degree of hydration of the tissue and, because much of the bound water of cartilaginous tissues may be associated with mucopolysaccharide, it seemed possible that cortisol might be acting on the synthesis of the polysaccharide component of the intercellular matrix. This possibility was supported by the observation that rudiments cultivated in the presence of cortisol ($2{\cdot}1 \times 10^{-7}$ M, or less) exhibit particularly intense toluidine blue staining[3], although there are now several reports (reviewed by Dziewiatkowski[5]) of an inhibition of polysaccharide synthesis in connective tissue, with reduced metachromasia, by high levels ($1–2 \times 10^{-4}$ M) of cortisol. Whitehouse and Lash[6,7] have also described inhibition of sulphation without interruption of polysaccharide synthesis.

Experiments were made to decide whether cortisol, at physiological concentrations, has any effect on the synthesis of polysaccharide by cartilaginous limb-bone rudiments cultured *in vitro*.

In each of a series of six experiments tibiae and femora from two 7-day-old chick embryos were cultivated on stainless steel grids[8] at 37·5° C. A chemically defined medium (*BGJ* 4) (ref. 9), modified by the inclusion of sulphur-35-labelled sodium sulphate, was used. Four bones from each set were cultivated in medium which also contained cortisol (0·1–0·001 μg per ml., that is, $2{\cdot}1 \times 10^{-7}$ M–$2{\cdot}1 \times 10^{-9}$ M), and several bones from each batch of eggs were immediately dried as zero-time

The medium contained sulphur-35 labelled sulphate giving 5,460 c.p.s. per ml., or 182 c.p.s. per μg sulphur, as 30·1 μg sulphur atoms were present per ml. Quantities of uronic acid are expressed as glucuronolactone, and the calculation of the quantity incorporated during the culture period is based on the presence of 19·5 μg in a group of zero-time control bones

controls. The explants were re-fed and gassed (with air + 5 per cent carbon dioxide) at intervals of 2 days.

After 6 days the rudiments were removed from the grids, rinsed in balanced salt solution, blotted and weighed. Each set of explants was reweighed after drying at 60° C *in vacuo*, and was then digested with papain[10]. The digests were diluted to 5·0 ml., 0·1 M with respect to sodium sulphate, and sampled for estimation of uronic acid[11]. Total radioactivity also was measured, after plating out, by means of a windowless scintillation counter, and appropriate corrections were made for self-absorption and decay.

Acidic polysaccharide was precipitated from the digests (3·5 ml.) by the addition of cetylpyridinium chloride solution[12] (0·2 ml., 1 per cent) and, after centrifugation, the clear supernatants were sampled for measurement of non-polysaccharide sulphur. The detergent–polysaccharide complexes were washed with sodium sulphate solution (0·1 M), and then redissolved in 1 M sodium chloride containing a little ethanol. The free polysaccharide was precipitated with ethanol (four volumes). A solution of the polysaccharide was taken for measurement of uronic acid content and radioactivity. The results of two typical experiments are presented in Table 1.

It can be seen that the presence of cortisol in the culture media did not have any effect (within the limits of accuracy attainable) on the ratio of sulphate to uronic acid in newly synthesized polysaccharide. The ratio of sulphur atoms to residues of glucuronic acid was close to unity, as would be predicted from the composition of chondroitin sulphate.

Cortisol inhibited polysaccharide synthesis as a whole, however; the extent of inhibition was 35 per cent at 0·1 μg per ml. (the mean of two experiments), 10 per cent at 0·01 μg per ml. (the mean of two experiments) and 3 per cent at 0·001 μg per ml. (in a single experiment).

Whitehouse and Lash[6,7] described the production of an incompletely sulphated chondroitin sulphate by chick somites in an *in vitro* system, when cortisol ($1·5 \times 10^{-4}$ M) was present, but in experiments with slices of bovine cartilage and cornea, Whitehouse and Borström[13] found cortisol to inhibit polysaccharide synthesis and sulphation equally. This latter finding is in agreement with work on skin[14] and other tissues[5].

It has already been reported by Reynolds[3] and by Dingle, Fell and Lucy[4] (in apparent contradiction of Schryver[2]) that total polysaccharide synthesis is inhibited by 0·1 μg per ml., or less, of cortisol, and this is confirmed by the present work. It is interesting that Whitehouse and Lash[6] detected no inhibition of uronic acid incorporation in their system, with cortisol at 720 times this concentration.

The possibility that the kind of sulphated polysaccharide synthesized by the chick limb-bone rudiments might be altered by cortisol was investigated in some unpublished work[15]. The glucosamine to galactosamine ratio in polysaccharide from bones cultured in the presence or the absence of cortisol, or directly *ex ovo*, was determined by a modification of Scott's method[16], and in each case only 3–5 per cent of the total hexosamine was glucosamine—the remainder was galactosamine. This suggested that the polysaccharide of the cartilaginous rudiments from each group was almost exclusively chondroitin sulphate. This finding is in contrast with that of Glick *et al.*[17], who used an *in vitro* system based on that of Lash, Holtzer and Holtzer[18].

In summary, this work shows that cortisol, at near-physiological concentrations, can reduce the synthesis of sulphated polysaccharide in cartilaginous bone rudiments in culture. This represents an extension of the many previous reports of inhibition at much higher concentrations of steroid.

No substantial disturbance of the expected ratio of sulphate to uronic acid was detected, and the results do not explain why the cortisol-treated rudiments were less hydrated than their paired controls.

In vivo Complex Formation of Actinomycin *D* and Deoxyribonucleic Acid

ACTINOMYCIN *D* (AMD) has been shown to inhibit the ribonucleic acid (RNA)-polymerase activity of bacterial cells. This inhibition is considered, at present, to represent the sole mechanism by which this agent inhibits cell division[1]. It appears to result from the formation of complexes between the antibiotic and deoxyribonucleic acid (DNA)[2]. Following parenteral administration to animals the antibiotic appears to possess similar activity, but differs in that high doses are required and the effects are reversible[3]. When administered to rats which have undergone partial hepatectomy, the expected subsequent mitotic activity can be eliminated[4].

It remained, therefore, to demonstrate that the mammalian cell activity of AMD is mediated by the same mechanism as in bacteria, and to explain these differences we have isolated DNA from the livers of rats previously treated with AMD and measured the priming activity of the DNA in a bacterial RNA-polymerase system.

This activity was significantly reduced when compared with DNA isolated from untreated rats and was restored by separation of the AMD. Similar parenteral doses demonstrated their expected inhibition of mitotic activity. The priming activity of liver DNA from untreated rats was inhibited after *in vitro* addition of AMD to a degree similar to that previously reported using thymus nucleic acid.

AMD was dissolved in sterile water at a concentration of 200 μg/ml. and the solution injected by way of the femoral vein. Animals which were investigated for the effect of AMD on mitosis were subjected to 70 per cent hepatectomy as described by Higgins and Anderson[5] and the antibiotic was administered simultaneously. Colchicine was administered intraperitoneally (1 mg/kg) at 25 h and the animals were killed at 31 h. Sections of liver were prepared and studied by standard histological techniques for mitotic activity. Liver nuclei were prepared by the triton extraction of Hymer and Kuff[6] and were free from cytoplasm when examined under phase microscopy. These were layered above caesium sulphate solutions and the DNA obtained by ultracentrifugation[7]. Such preparations were tested in an RNA synthesizing system utilizing the polymerase of *M. lysodeikticus* as described by Nakamoto, Fox and Weiss[8]. The incorporation of tritiated uridine triphosphate (UTP-^{3}H) was utilized as a measure of RNA production. The AMD–DNA complexes were extracted by precipitation in 3 : 1 isopropanol, followed by centrifugation. This process was repeated when sufficient DNA was available and the DNA finally dissolved in 0·001 M sodium citrate–0·01 M sodium phosphate buffer.

DNA isolated from liver cell nuclei of rats which had received AMD had a decreased ability to prime the polymerase system. This decrease was roughly proportional to the dose of the antibiotic administered (Table 1). The DNA isolated as described above was a highly hyperchromic material, apparently free of protein contamination as determined by ultra-violet spectrum analysis. A maximal inhibition was achieved with a dose of 300 μg/kg as complexes isolated from animals receiving doses as high as 1 mg/kg failed to show a significantly increased inhibition. Histological examination indicated that 300 μg/kg was also the minimal dose which invariably inhibited the mitotic response in rats following 70 per cent hepatectomy.

Table 1 RNA-POLYMERASE PRIMING UTILIZING *in vivo* FORMED COMPLEXES OF AMD AND DNA

Dose (μg AMD/kg)	Incorporation* (per cent)	Extracted* (per cent)	Expected mitosis† (per cent)
100 (3)‡	52–64		‡(6) 85–100
200 (2)	33·7–37·7	§(1) 56·9	(6) 36–86
300 (4)	23 4–29	(1) 42·0	(6) 0
1,000 (2)	20·1–25·4		(3) 0

* Percentage incorporation of UTP-^{3}H into RNA synthesized as compared with the priming by untreated liver DNA.
† Compared with average mitotic counts of (twelve) partially hepatectomized, untreated rats.
‡ Number of animals tested.
§ Number of extractions performed.

Extraction of these *in vivo* formed complexes by isopropanol precipitation reduced the degree of inhibition of priming ability. The number of extractions was limited by the amount of material available and complete restoration was not achieved as with *in vitro* formed complexes (Tables 1 and 2). No residual damage to DNA could be demonstrated by measurement of hyperchromicity.

The DNA isolated from rat liver nuclei proved to be highly active in RNA–polymerase systems, and was at least as active as standard thymus nucleic acid preparations. Addition of AMD to this DNA before its addition to the polymerase system resulted in inhibition of RNA production proportional to the quantity of the antibiotic added (Table 2). Extraction of this system with propanol precipitation restored the priming ability of the DNA.

It has been possible to isolate the complex which is formed between parenterally administered AMD and rat liver DNA, and we have demonstrated an inhibition of its priming ability. The use of the triton method of nuclear preparation and caesium sulphate gradient ultracentrifugation limits the exposure of the complex to extraction by numerous solvents or by cytoplasmic components. The maintenance of the complex throughout the preparation, however, indicates considerable binding strength of the AMD to DNA since the centrifugation itself is capable of freeing the nucleic acid of its tightly complexed proteins. Our inability to detect the AMD on spectroscopic examination of the complex fits well with the concept that the binding sites to which the antibiotic is complexed are of high functional activity, but of low capacity. These would represent, therefore, the tight binding sites as described by Gellert *et al.*[9].

That the inhibition is based solely on the presence of AMD was demonstrated by the return of priming ability of the isolated DNA on extraction of the antibiotic. More extensive extraction of the *in vitro* formed complexes in several instances completely restored priming ability. This indicates a lack of residual damage to the DNA.

Table 2. RNA–POLYMERASE PRIMING UTILIZING AMD–DNA COMPLEXES FORMED *in vitro*

mμM AMD/ml.	Incorporation* (per cent)	Extracted* (per cent)
0 500	2 5–4 7	†(2) 29 4–37 8
0·250	12 7	
0 125	30·2	
0 100	28 3–38 7	(2) 62·5–62·8

0 005	87·0	(2) 102

* Percentage incorporation of UTP-^{3}H into RNA synthesized as compared with priming by untreated liver DNA.
† Number of extractions performed.

It has previously been reported that the mitotic activity which normally follows partial hepatectomy is eliminated by high doses of AMD[3]. It has been indicated that this effect results from the inhibition of synthesis of RNA and the failure of the subsequent production of the enzymes involved in the synthesis of DNA. Support for this concept of inhibition of RNA synthesis *in vivo* is offered by the present data, but the type of RNA synthesis so effected is not indicated. The dose of antibiotic optimal for inhibiting mitotic response in liver cells, 300 μg/kg, also represents approximately the maximal binding capacity of DNA for this agent *in vivo*. This may reflect the maximal capacity of AMD to compete with nuclear proteins for binding sites or the maximal number of binding sites of high affinity for the antibiotic. Our results show that AMD acts within the animal in a fashion similar to that manifested in bacteria and isolated cells. The mechanism of differences between the two systems has not yet been clarified.

Reduced Benzo(a)pyrene and Phenolic Content of Smoke from Experimental Cigarettes

THE properties of tobacco and non-tobacco leaves can be modified by subjecting these leaves to a series of chemical extractions which strip the whole leaf, or shredded leaf, to almost pure cellulose. This extraction process removes unhealthy substances and improves the flavour and aroma of such leaves when they are used as a smoking product. The extracted leaf is reconstituted, preferably to its original weight, by adding back non-toxic chemical agents which enhance the burning qualities, flavour and aroma.

In recent years increasing statistical evidence has associated cigarette smoking with increased death rates from lung cancer and other diseases, notably coronary heart disease, emphysema and chronic bronchitis[1]. Recently, an advisory committee to the Surgeon General of the United States claimed to have established a causal relationship between cigarette smoking and lung disease.

Nearly 500 different chemical compounds have been isolated from cigarette condensate, including numerous polycyclic, aromatic, and other organic and inorganic compounds. Many of these compounds are carcinogenic and toxic when assayed on animals.

Polycyclics generally initiate the carcinogenic process and several polycyclic hydrocarbons are complete carcinogens. Because only relatively small amounts of polycyclics are present in the unburned leaf, they must be formed during the burning process from materials inherent in the leaf[2]. Polycyclics may be formed on pyrolysis of cellulose, lignin, pectin, starch, sucrose, glucose, and fructose and of citric, malic, and oxalic acids. Pyrolysis of tobacco paraffins at temperatures higher than 600° C yields polycyclics[3]. Incomplete pyrolysis of sterols may also produce polycyclics[4]. An efficient extraction process should remove sterols, paraffins, and other possible precursors of polycyclics. Recent evidence indicates that polonium-210 may also initiate the carcinogenic process[5]. Polonium-210 should also be removed with an adequately designed extraction process.

The polycyclic fractions from cigarette smoke condensate account for less than 10 per cent of the carcinogenic activity of cigarette tar. It is believed that co-carcinogenic compounds are responsible for more than 90 per cent of the carcinogenic activity in the smoke condensate[6]. Several phenols are known to be co-carcinogens[7]: phenol, dimethylphenol, ethylphenol and *ortho-*, *meta-*, and *para-*cresol are all present in cigarette smoke condensate[8]. Other types of substances as yet unidentified may also be promoting substances. Co-carcinogens have been demonstrated in the alkaline extracts of unburned tobacco[9].

The burning process may release co-carcinogens by either dry distillation or by incomplete destruction of usually non-carcinogenic compounds. (Dry distillation is the volatilization of substances which arises because of high temperatures near the burning zone of an ignited cigarette.) These substances are transmitted unchanged to the mainstream smoke. A second way in which co-carcinogens may arise is through incomplete pyrolysis of materials inherent in the leaf. Rearrangements, oxidations, cracking, dehydrogenation and condensation reactions may convert usually non-carcinogenic compounds into carcinogens.

Sun-cured soybean leaves were first shredded with a model 00 Himhoff-cutter at a standard cut of 30 cuts/in. The shredded leaves were placed in stainless-steel wire-mesh baskets, and these baskets were raised or lowered frequently out of larger stainless-steel drums containing the solvents. The proportions of dry leaf to solvent were kept constant. Twenty millilitres of extracting solvent were used per gram of initial unextracted shredded dry leaf. All the extractions were carried out for 50 min at 55° C. The leaves were first rinsed twice with water under the aforementioned conditions. These two rinse solutions were discarded. Fresh water was heated to 55° C and added to the stainless-steel containers. Sodium chlorite was added until its concentration was 1 per cent. The *p*H was adjusted to 4 with glacial acetic acid and the leaves were again lowered into the solution. After discarding the bleach solution, the leaves were rinsed twice with water to remove the bleach. Acetone was the final extracting solvent. The baskets were then raised and allowed to drain. The shredded leaves were removed from the baskets and air dried.

Table 1. RESULTS OF PHENOL, BENZO(*a*)PYRENE, AND TAR ANALYSES OF EXPERIMENTAL CIGARETTES AND CONTROL AMERICAN TOBACCO CIGARETTES

Cigarette	Tar/cig. (mg)	Phenol/cig. (mg)	BP/cig. (γ)
Non-tobacco	10·6	0 046	1·50
Tobacco	38·6	0·27	6·15

The shredded leaves were then flavoured with several ingredients to ensure the proper hydroscopic and burning qualities. In this experiment the compounds used were: 10 per cent invert sugar, 5 per cent glycerol, 2 per cent honey, 1·5 per cent St. John's bread (that is, ground meal from the ripe fruit of *Ceratonica siliqua*), 1 per cent cocoa and 3 per cent potassium nitrate (selected on the basis of their low benzoid content). The ingredients were sprayed on to the shredded leaves in a rotary drum. To ensure a good tobacco flavour, various non-carcinogenic fractions of tobacco extract could be added to the flavouring mixture[10]. 50 lb. completed leaves was adjusted to a humidity content of 13 per cent. Cigarettes of the thus prepared flavoured shredded leaves were made in an American Machine and Foundry cigarette maker.

85-mm cigarettes were smoked on a standard Ecusta smoking machine. Standard American cigarettes were used as controls. Smoking parameters were set at a 35 ml. puff of 2 sec duration at 1 min intervals. The average butt length was 22 mm. Tars were collected on a previously weighed Cambridge filter. After the tar had been collected, the filter was weighed again. Phenols were determined by the method of Oakley *et al.*[11]. Benzo(*a*)pyrene analyses were made by the method of Wynder[12]. Results of the phenol and benzo(*a*)pyrene analyses are given in Table 1.

The extraction process reduces the tar content per cigarette to only 27·4 per cent of a standard American cigarette (Table 1). Phenols were also reduced to 17 per cent of the control. The reduction of benzo(*a*)pyrene suggests that it arises during the burning process through re-arrangement of complex polyphenols, steroids or other precursors inherent in the leaf. The extraction process also almost completely removes amino-acids, other nitrogen compounds and sulphur compounds. Toxic compounds, such as nitrogen dioxide, methyl nitrite, hydrogen cyanide and hydrogen sulphide are also probably considerably reduced in concentration in the mainstream smoke.

The great reduction of tar, phenols, benzo(*a*)pyrene and toxic substances indicates that it is possible to design a relatively safe cigarette.

PHARMACOLOGY

Goitrogenic Activity of Onion Volatiles

GOITRE is known to be prevalent in the Lebanon, mainly in the high mountain valleys[1–5]. In an investigation of the population of an endemic area in the Lebanon, Cowan *et al.*[6] found that iodine deficiency was the primary cause of the endemic goitre. This deficiency could be intensified by the consumption of goitrogenic foods which cause either an increased iodine excretion or an inhibition of the biosynthesis of the thyroid hormone, thyroxine.

Two sulphur-containing substances, thiourea and thiouracil, have been found to inhibit the iodization process of thyroxine[7]. In addition, thiocyanate and thiooxazolidone-forming substances, in plants mainly of the Cruciferae family, have been shown to be goitrogenic[8–11]. However, there have been no reports on the possible goitrogenicity of onions, although sulphur compounds are known to be the principal components of their oils[12,13].

Onions are grown extensively in the Lebanon and are consumed in great amounts by the Lebanese people; thus an investigation of the possible goitrogenic activity of this plant is important. Saghir *et al.*[14] found that propyl disulphide is the main volatile constituent of certain food onions (common onion, *Allium cepa*; leek, *A. ampeloprasum*; Japanese bunching onion, *A. fistulosum*; and chive, *A. shoenoprasum*). This compound was therefore selected to be tested for its goitrogenic effect. Preliminary experiments indicated that 5 μl. and 10 μl. doses of the chemical slightly inhibited thyroid function in rats. The present work was initiated to investigate the effects of high levels of this sulphide.

Synthetic *n*-propyl disulphide (PDS) was obtained in pure form from Eastman Organic Chemicals; previous work had shown this compound to be identical to that found in onions[12,13]. For the assessment of goitrogenicity, the "acute" test described by Langer and Stolc[15] was used. The experimental animals were young female albino rats of the Sprague–Dawley strain, weighing about 150 g. Because the test was based on short-period (3 h) values for radioiodine uptake, iodine-deficient animals were used so that the control values would be relatively high. The rats were rendered deficient in iodine by maintaining them on a low iodine diet for 6 weeks. This diet was complete except for iodine, and the animals grew normally during the period of iodine depletion.

Five animals were assigned to each of seven test groups, according to a randomized block design, based on body weight. "Normal" uptake values were obtained from a control group which received only corn oil (since the test material was an oil). To check the validity of the test by demonstrating definite inhibition of thyroid function, two groups of rats were treated with two levels of a known goitrogen, propyl thiouracil (PTU).

The animals were fasted overnight before the experiment; the appropriate amounts of corn oil, PTU or PDS (Table 1) were then administered by stomach tube. 1 h later, each rat received, by intraperitoneal injection, 1 μc. of carrier-free sodium iodide labelled with iodine-131 in 0·5 ml. of 0·9 per cent saline solution. Exactly 3 h later, the animals were killed with chloroform and the thyroids were removed and weighed. Each gland was digested overnight at 50° C in a tube containing 2 ml. of alcoholic potassium hydroxide (potassium hydroxide, 5 g; water, 50 ml.; ethanol, 100 ml.). Total radioactivity was measured in each tube using a well-type crystal scintillation counter (Baird-Atomic). Percentage uptake was calculated by comparing the counts per mg thyroid tissue with those obtained from a standard dose counted at the same time as the thyroid digests.

The results are shown in Table 1. It is clear that at all levels used, *n*-propyl disulphide inhibited thyroid function significantly as is shown by the low values for uptake of iodine-131 in the treated animals. These low values were similar to those obtained by treatment with PTU. These observations point to the possibility that the consumption of food onions high in PDS may contribute to the incidence of goitre in countries such as the Lebanon where iodine intake is low. Further work is planned to investigate the possible goitrogenic effects of other sulphide radicals known to be constituents of other *Allium* species.

Table 1. EFFECT OF VARIOUS LEVELS OF *n*-PROPYL DISULPHIDE AND PROPYL THIOURACIL ON THE UPTAKE OF IODINE-131 IN RATS

Treatment	Dose	Average percentage uptake of iodine-131 per mg tissue*
Corn oil	100 μl.	1·176
PTU	1 mg	0·060
PTU	2 mg	0·080
PDS	60 μl.	0·070
PDS	120 μl.	0·080
PDS	180 μl.	0·087
PDS	240 μl.	0·103

6-Hydroxyskatole Glucuronide, a Skatole Metabolite

THE metabolism of 6-hydroxylated indoles is of interest in view of their possible psychotoxicity as reported by Szara[1] and the finding, originally by Leyton[2], that 6-hydroxyskatole sulphate is excreted in larger amounts by schizophrenic patients.

Hydroxylation and subsequent conjugation with either sulphate or glucuronic acid has been shown to be a pathway for the detoxification of a number of indoles. Skatole has been shown to undergo hydroxylation primarily in the 6 position and subsequent conjugation with sulphate[3]. Melatonin, another 6-hydroxylated indole, is excreted both as the sulphate and the glucuronide[4]. This report presents evidence that 6-hydroxyskatole is also excreted as the glucuronide.

6-Hydroxyskatole was prepared according to the method of Heacock[5] from 6-benzyloxygramine by catalytic hydrogenation. The compound was administered to 150-g Sprague-Dawley male rats in doses of 0·1, 1, 10, 25 and 50 mg/kg. Urine was collected at 2-h intervals

and subjected to paper chromatography and analysis for 6-hydroxylated indoles. Chromatography was ascending on Whatman No. 1 paper using isopropanol–ammonia–water, 10 : 1 : 1. Compounds were located with the acidic diazo reagent of Jepson[6] and with Ehrlich's reagent.

Quantitative estimations were carried out using 0·1 ml. urine, 0·9 ml. water and 5 ml. acidic diazo reagent prepared as described by Sohler *et al.*[7]. The colour was extracted into butanol and read at 415 mμ for the conjugated compounds and 530 mμ for free 6-hydroxyskatole. 'Unknowns' were compared with standard curves prepared from 6-hydroxyskatole sulphate for the conjugates and 6-hydroxyskatole for the free compound.

Chromatography of urine samples showed three 6-hydroxylated indoles to be present in the urine after the rats received 6-hydroxyskatole. The first compound (R_F 99) is free 6-hydroxyskatole[2]; the second (R_F 73) is the sulphate conjugate, while the third (R_F 15) proved to be the glucuronide of 6-hydroxyskatole. The R_F 15 material was isolated from urine by paper chromatography on Whatman 3 *MM* paper using the isopropanol–ammonia–water system. It was then eluted and chromatographed once more on Whatman 3 *MM* paper using a butanol–pyridine–water (60 : 60 : 60) solvent system. Acid hydrolysis of the purified material yielded a new spot which reacted positively with naphthoresorcinol reagent and on subsequent chromatography proved to be glucuronic acid. This spot was also obtained when the purified material was treated with 'Glusulase'—an enzyme preparation having both glucuronidase and sulphatase activity.

Fig. 1 illustrates the effect of 'Glusulase' on the 6-hydroxylated urinary metabolites. On 'Glusulase' treatment both sulphate and glucuronide spots tended to disappear while the spot of free 6-hydroxyskatole increased. 6-Hydroxyskatole would seem to be eliminated quite rapidly in the rat in the form of the free compound and the sulphate and glucuronide conjugates—the rate of excretion is maximal during the first 4 h, then levels off and is almost complete within 12 h.

Trace amounts of the glucuronide conjugate were found in human subjects who excreted large quantities of 6-hydroxyskatole sulphate. The presence of the glucuronide was established by concentrating urine samples tenfold. The concentrate was treated with urease and afterwards 200 lambda of the concentrate was spotted on Whatman 3 *MM* and run in the isopropanol–ammonia–water system. The glucuronide was detected with Ehrlich's and diazo reagent and its identity as the glucuronide was established with naphthoresorcinol reagent.

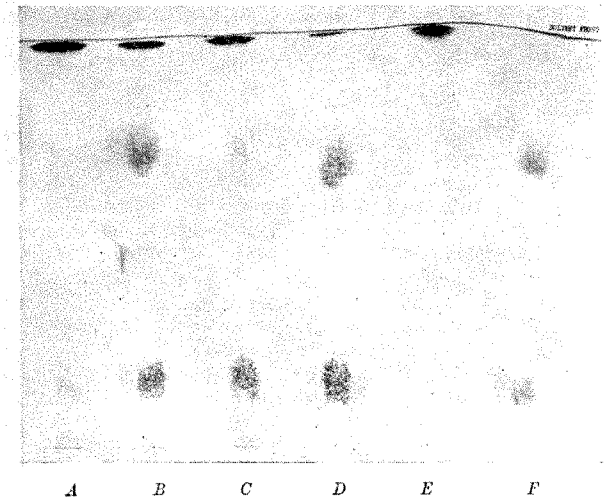

Fig. 1. Effect of 'Glusulase' on 6-hydroxylated indole metabolites in rat urine after administration of 6-hydroxyskatole. Urine samples were collected at 2-h intervals, 30 lambda of urine or its 'Glusulase'-treated equivalent was spotted. *A*, 2-h urine treated with 'Glusulase'; *B*, 2-h urine; *C*, 4-h urine treated with 'Glusulase'; *D*, 4-h urine; *E*, 6-h urine treated with 'Glusulase'; *F*, 6-h urine. Solvent system, isopropanol–ammonia–water (10 : 1 : 1)

Conjugation with glucuronic acid would seem to be an alternate pathway for the elimination of 6-hydroxyskatole acting in both rat and man.

Oral Hypoglycaemic Activity of an Anhydroformaldehyde Aniline–Insulin Mixture

TWENTY-FIVE to thirty per cent of diabetic patients require insulin to remain alive and well. In the main these patients have the juvenile-onset type of diabetes mellitus and treatment for many years is normal. So far, the insulin they require can only be administered parenterally, despite many attempts in the past 40 years to circumvent the injections needed and the physical risks and psychological trauma involved[1].

It was of interest, therefore, when Ferguson[2] reported that the oral administration of a mixture of insulin and an anhydroformaldehyde–aniline (AFA) compound caused hypoglycaemia in rabbits, but the AFA compound alone was without effect. The implication that this compound allows insulin to be absorbed in a physiologically active form is of such importance that the work was repeated in our laboratories.

The AFA compound is formed by the reaction between aniline and formaldehyde, the primary product being the Schiff's base. This immediately polymerizes and under suitable conditions yields 1,3,5,-triphenylhexahydro-*s*-triazine[3], which Ferguson refers to as "anhydroformaldehyde–aniline" and gives the formula as

This can be isolated as a white crystalline material with a melting point of 141° C (ligroin).

In the present experiments, male rabbits of the New Zealand White strain (3–3·5 kg) were used, either fed or fasted for 18 h, as shown in Tables 1–3. All drugs were administered by stomach tube. Blood was taken from the marginal ear vein for measurements of the sugar-levels ('Autoanalyser' method). Samples were taken in duplicate before and at intervals after the AFA-insulin mixture or control solutions. Three separate experiments were performed.

AFA was prepared as described by Ferguson from aniline hydrochloride and commercial formalin, dried, powdered and mixed with commercial insulin ('Iletin' regular, 80 U. per ml.). This mixture was administered by stomach tube to both fed and fasted rabbits. Control solutions of

insulin, AFA alone and water alone were also given. No signs of illness were observed in any animal. Results are shown in Table 1. No hypoglycaemic effect of the mixture could be demonstrated.

Table 1. Effect of Oral AFA–Insulin Mixture and Control Solution on Blood Sugar of Fed and Fasted Rabbits

Drug	No. of animals		Blood sugar mg per 100 ml. Hours after administration 0	1	2	3	4	5
AFA 200 mg	4	fed	97	107	109	102		91
	4	fasted	81	77	81		76	81
Insulin 400 U.	4	fed	97	102	102	98		94
	4	fasted	89	87	85		82	90
Water 10 ml.	4	fed	99	99	97	95		92
	4	fasted	74	75	79		76	90
AFA 200 mg plus	4	fed	91	101	95	91		88
100 U. insulin	4	fasted	80	80	80		74	85
AFA 200 mg plus	4	fed	90	91	87	84		85
200 U. insulin	4	fasted	72	76	79		76	86
AFA 200 mg plus	4	fed	88	94	91	87		81
400 U insulin	4	fasted	78	81	81		80	86

In the second experiment, aniline was made to react with formalin in 65 per cent ethanol and the commercial insulin added after the formalin, as described by Ferguson. This suspension was administered to the rabbits without further processing. This method of preparation had been shown to be as effective as the first. The results in fasted rabbits are shown in Table 2. Thirty per cent ethanol was used as control, as this is required in the preparation to keep the reactants in solution. No signs of illness were observed in any animal. No hypoglycaemic effect of this preparation could be demonstrated.

Table 2. Effect of Oral AFA–Insulin Mixture (Method 2) and Controls on Blood Sugar of Fasted Rabbits

Drug	No. of animals	Blood sugar mg per 100 ml. Hours after administration 0	1	2	3	4	6
AFA plus 200 U. insulin	6	80	80	79	81	82	81
AFA alone	4	80	81	81	81	83	86
30 per cent ethanol 7 ml.	4	74	73	72	73	75	76

In the third experiment a pure sample of the anhydroformaldehyde–aniline compound was prepared according to the method of Miller and Wagner[4]. Measurements of its melting point and microanalysis give results which are similar to those with the compound prepared by the first method of Ferguson. Results are shown in Table 3 of the effect of this compound on the blood sugar-levels of fasted rabbits.

Table 3. Effect of Oral AFA–Insulin Mixture (Method 3) and Controls on Blood Sugar of Fasted Rabbits

Drug	No of animals	Blood sugar mg per 100 ml. Hours after administration 0	1	2	3	4	6
40 mg AFA plus 800 U. insulin	4	68	73	67	71	69	72
200 mg AFA plus 400 U. insulin	4	79	80	80	82	81	83
200 mg AFA alone	4	75	77	78	78	74	80
2 g AFA alone	4	72	71	70	71	70	72

These results clearly show that under our experimental conditions, the anhydroformaldehyde–aniline compound as described by Ferguson does not allow insulin to be absorbed in a physiologically active form. There are two aspects of the work of Ferguson, however, which require amplification.

First, he states that fasting rabbits, before administration of the AFA–insulin complex, have blood sugar-levels of 120–140 mg per 100 ml. This is far in excess of any levels we have seen in starved rabbits. Secondly, in the second method for the preparation of AFA–insulin, ethanol was administered with insulin. It has already been shown that 20 per cent ethanol facilitates the absorption of insulin[5,6]. In a small pilot experiment in four fasted rabbits, we were able to show that ethanol in the concentration used in our second experiment (30 per cent), when given with insulin by stomach tube, causes a small but significant fall in blood sugar-levels after 1 h ($P < 0{\cdot}02$). This is not seen with insulin or ethanol alone. However, this effect of ethanol could not explain the reported hypoglycaemia produced by the first preparation of the AFA compound.

Our results do not support the claim that anhydroformaldehyde–aniline compounds facilitate the absorption of insulin in a physiologically active form.

PHYSIOLOGY

Velocity and Force of Some Karate Arm-movements

A special aspect of Karate (a Japanese technique of self-defence and, in competitions, a game with very strictly regulated rules in which the partners are not allowed to strike each other) can sometimes be seen as a demonstration: the Karateka breaking bricks, tiles or blocks of wood with a strike of his bare hands, feet, fingers or forehead[1], the object being supported only at its ends.

The principles of the dynamics of a suddenly applied force on a supported beam are applicable here. When a falling body strikes a beam supported at its ends with a certain velocity the beam will break if the force per unit area due to the collision is greater than the maximum stress-resistance of the material of the beam. Thus one might expect that the man who breaks a brick or other solid object with a stroke of his bare hands or feet will: (1) Develop a great velocity of movement of the mass of his arm or leg at the moment of the impact. (2) Keep a very hard and relatively small contact area between hands or feet and the object so as to concentrate the force of the impulse on a small surface. (3) Have a great determination and courage to strike powerfully at a hard object with his bare hands or feet. These three 'actions' may be singled out or work together.

We performed some studies on the velocity of some Karate movements (striking) and on the reaction force when breaking objects with the bare hand. The velocity of movement was calculated from photographs taken with the aid of a calibrated stroboscopic lamp. The movements, the velocity of which was measured, were principally accomplished in a plane parallel to the photographic plate. The force was measured with a strain-gauge device on which the objects and their supports were placed. The objects were supported at their short ends. The subjects were well-trained Karatekas (subject No. 2, for example, is one of Japan's best Karate men). They performed their movements in the usual way, without being impeded by the measuring devices. Special attention should be given to the way the Karateka holds his hand when he is going to break a brick or a plate. Breaking a brick is done with a hyper-dorsiflexed and pronated hand, the fingers almost stretched. During the impact the place of contact is the area over the pisiform bone of

the wrist-joint. A plate is struck either with the tops of the forefinger, the middle finger and the ring finger of the semi-stretched hand and the fingers held tightly together—the tops of the fingers almost forming one plane—or with the fist; in this case the knuckles of the forefinger and the middle finger are the places of contact. In these experiments the fist was used and one plate was broken. However, usually more plates are broken at one time when striking with the fist. In order to offer some idea of the velocity of movement and the breaking force of the Karateka in comparison with subjects not experienced in Karate we shall give some data of two control subjects (both moderately trained) who were asked to make the same movements.

Table 1 presents the maximal linear velocity of the fingers during a stroke through the air as well as the force with which bricks and plates were hit and/or broken with the hand and the fist. It must be noted that the data of the velocity do not apply to the experiments in which the bricks or plates were broken.

From these data it can be said that: (1) The velocity of the arm movement of the Karatekas is about 25 per cent higher than that of the control subjects. (2) The force of the Karatekas and control subjects with which the bricks were hit did not differ much. In some cases the Karatekas could not break the brick even with greater forces probably because of the inhomogeneity of the material. The data give a good idea of the magnitude of the force that can be exerted with a stroke of the bare hand on a hard object. (3) The forces necessary to break one plate are not large. Also in this case one of the control subjects broke one plate (we did not measure the force which he exerted).

As to the hard contact surface, the following is tentatively suggested: usually the knuckles of the forefinger and the middle finger are covered with a large amount of callosity, which is, in our opinion, less hard than the knuckles covered only by the skin. This finding seems to be in conflict with the principles of the dynamics of an impulse which state that with a definite change in momentum the force is greater the shorter the time of the impulse. On the other hand, the powerful strokes will probably damage the hands when these are not covered with compressible material (tissues). Therefore this callosity can be considered to offer protection against knuckle damage (the Karatekas mostly have special training to develop this callosity). This idea is supported by the fact that the skin over the pisiform bone was not very callous in any of the Karate subjects, nor were the tops of the fingers, although these parts of the hand were also used during the breaking of objects at other events. Probably at those places the skin with the underlying tissues is sufficiently thick to protect the underlying bone. It is also supported by the fact that the Karatekas often put a rather thick cloth on the pile of the objects, especially when there are a number of objects to be broken and they must strike very hard. It is probable that the factor of courage is of great importance because it can be seen that the two control subjects who were unfamiliar with Karate dared to strike a brick with about the same force as the Karate specialists. Furthermore, as already reported, control subject No. 1 broke one plate of the same size with his fist.

Table 1. MAXIMUM VELOCITY AND FORCES OF SOME KARATE MOVEMENTS (STRIKING)

Maximum velocity of the fingers during a stroke through the air

Karate subject	Velocity (km per h)
1	51
2	49
3	46
Control subject	
1	40
2	39

Forces during breaking of objects with a stroke of the bare hand

Karate subject	Object	Force (kg)		Object	Force (kg)	
1	One brick*	58	(broken)	One plate†	29	(broken)
1	,, ,,	89	(not broken)			
2				,, ,,	13	(broken)
3	,, ,,	47	(broken)			
3	,, ,,	58	(not broken)			
Control subject						
1	,, ,,‡	60	(broken)			
2	,, ,,	60	(broken)			

* Size of the brick: 200 × 105 × 55 mm. Material, red baked clay.
† Size of the plate: 270 × 240 × 20 mm. Material, deal.
‡ Sandstone brick (softer than red baked clay).

Finally, we performed some additional measurements, using laboratory apparatus, of isometric muscle forces during arm bending and knee stretching, as well as of maximal velocity of arm bending. The results for the Karatekas were not significantly different from those of the controls.

In conclusion, we believe that Karatekas develop a greater speed of movement than is normal and effect a hard and relatively small contact area between their hand or foot and the object they are striking. However, it is probable that good technique and a large amount of courage to strike powerfully a hard object are of equal or even greater importance.

We thank Mr. W. J. Reichert for his advice on the mechanical aspects of this work and Mr. A. C. A. Vissers for the construction of some of the apparatus.

Deposition of Inhaled Particles in Human Lungs

DURING the past 25 years, six independent groups of workers have measured the decrease in concentration of particles in exhaled air during steady breathing, while their subjects inhaled various aerosols, and have expressed their findings as a relationship between particle size and lung deposition. These results fall into two ranges, three of the groups of workers obtaining much higher values for deposition than the other three for particles between 0·5 and 6μ diameter. The difference cannot be explained by the nature of the particles or the method of breathing[1].

The techniques used in such work have recently been investigated, and it has been decided that there may be a substantial overestimate of lung deposition in the work of Van Wijk and Patterson[2] and of Dennis and Sawyer[3].

In these experiments, the sampling of the exhaled air proceeded continuously, with a thermal precipitator by the former and a conifuge by the latter, even while the subject was inhaling. Since the first part of the exhaled air comes from the dead space of the tidal airways, it will have deposited fewer particles in the lungs than the last part of the exhaled air, which has approached the lung alveoli. The concentration of particles towards the end of an exhalation is therefore much less than at the beginning and may even be zero. If sampling is continued during inhalation it is clear that about half the volume sampled may contain particles in a concentration below the average, so that an overestimate of lung deposition will arise. Among other factors, the extent of this error depends on the thoroughness of mixing of the exhaled air before reaching the sampling point; if complete mixing of the entire volume of each exhalate were possible, before the sample was taken, no error would result.

It is difficult to assess how much mixing took place in the box into which the exhalate of the subjects of Van Wijk and Patterson was passed, but a baffle was used to direct what was probably a laminar stream across the orifice of the thermal precipitator, which would therefore tend to receive sequential concentrations.

Dennis and Sawyer fed the exhalate through a glass bulb, which was in many cases smaller than the tidal volume, and sucked a sample through a conifuge from the

Table 1. ERROR DUE TO SAMPLING DURING THE PERIOD OF INHALATION

Tidal air volume (cm³)	Apparent average concentration in exhaled air divided by true value: Particle diameter (microns) 0·25	1·4	3·8	6·3
450	0·89	0·82	0·72	0·69
900	0·82	0·68	0·55	0·50
1,350	0·79	0·64	0·54	0·50

base of the bulb; it is therefore likely that the air sampled at the end of each breath and during the succeeding period of inhalation was substantially deficient in particles.

Estimates of the error which can arise in this way have been calculated from the experimental data of Landahl, Tracewell and Lassen[4] for human inhalation of aerosols of triphenyl phosphate. They give the percentage concentrations exhaled in four successive quarters of a breath; from these figures the ratio of the apparent average exhaled concentration to the correct value has been derived and is given in Table 1. The apparent value results when the average is taken over the entire breathing cycle with the ultimate, deficient part of the exhalate being sampled during inhalation.

The maximum error is 0·5 when the last part of the exhalate is free from particles.

This error probably accounts for the high values for lung deposition obtained by Dennis and Sawyer and by Van Wijk and Patterson. It cannot be the cause of an overestimate of total deposition by Brown, Cooke, Ney and Hatch[5], because they sampled fractions of exhaled breath with electrostatic precipitators which were ventilated only during exhalation.

Development of Neuronal Activity in Neocortex of the Kitten

MAMMALIAN cerebral cortex undergoes rapid structural changes during the postnatal period. Dendritic connexions increase in number and complexity, the volume of neurone somata increases, and myelination occurs in subcortical and cortical fibres[1]. Little is known about the functioning state of cerebral neurones during this period of rapid development. In kittens, spontaneous and evoked activity has been recorded from the cortical surface during the 'new-born' period, but such records have been difficult to interpret[2,3]. For example, it is not possible to be certain whether the activity recorded from surface originates in cortex itself, or is transmitted from subcortical structures. In the present investigations, recordings were obtained from single cortical neurones and from subcortical fibres in unanaesthetized, unrestrained kittens. The results indicate that large parts of neocortex in the kitten are electrically silent at birth, but that neuronal activity rapidly develops in the postnatal period. The early patterns of neuronal discharge show striking differences from those seen in adult animals.

The technique used was similar to that described by Hubel and by Evarts for recording from unanaesthetized, unrestrained adult cats[4,5]. A metal cylinder, to which a hydraulic microdrive could be attached, was implanted on the skull under general anaesthesia. Attachment of the cylinder to skull was secured by use of dental cement. The animals were allowed to recover from the anaesthesia before recordings were obtained. The microelectrodes used were glass-insulated platinum–iridium wires[6]. A stroboscopic light was used to evoke flash responses in visual cortex and in optic radiations. The electrocorticogram was recorded from stainless steel wires placed on the dura. Recordings were obtained from lateral and suprasylvian gyrus, and from geniculate radiation fibres. Twelve kittens, aged from 1 day to 2 weeks, were used in the investigations.

Activity was already occurring in subcortical fibre tracts at birth. In optic radiations, responses to flash could be recorded in neonatal animals, indicating that retina, optic nerves, and lateral geniculate neurones were capable of some degree of function at this age. The flashes were presented through closed eyelids. The latency from flash to unit discharge was considerably longer than in the adult, varying between 120 and 250 msec. In addition to evoked discharges, subcortical fibres in neonatal animals showed occasional spontaneous activity. This consisted of brief bursts, with intervening periods of silence which lasted for many seconds. Neighbouring fibres discharged synchronously during a burst of activity. Bursts were often associated with muscular twitches, and such twitches, which involved muscles of extremities, neck, face and ears, were very prominent when the kittens were asleep.

In contrast to the findings in subcortical fibres, cortical areas from which recordings were obtained showed no evidence of either spontaneous or sensory evoked neuronal activity during the first three days after birth. Occasional positive spikes of rather long duration (up to 20 msec) were observed as the electrode penetrated cortex. These persisted for only a few seconds, and showed a rapid decrease in amplitude. Such spikes probably represented injury discharges due to mechanical distortion of otherwise silent cortical neurones by the recording electrode. They differed from injury discharges in adult cortex in that rapid repetitive firing did not occur.

Both evoked and spontaneous activity appeared in cortical neurones at about the same time—between ages of 4 days and 2 weeks. Active cells were quite rare in 4–7-day-old kittens, and at times several penetrations of a whole thickness of cortex had to be made before an active neurone was encountered. Flash responses had a latency of 100 msec or longer. Inhibition of spontaneous firing by flash, which is a frequent finding in adult cortex[5], has not been observed in kittens less than 2 weeks old. However, the failure to see inhibition may be due to the very low rates of spontaneous discharge in immature neurones, rather than due to the absence of inhibitory connexions. Mean rates of spontaneous activity during the first two postnatal weeks ranged from only 1 spike/min to 1 spike/sec, as compared with a mean discharge rate of 7–8 spikes/sec in the same cortical areas in adult cats[7]. The pattern of spontaneous activity also showed differences from adult cortex. Cortical neurones in animals less than 2 weeks old characteristically discharged in brief bursts of 2–10 spikes, followed by prolonged periods of inactivity, which at times lasted for several minutes. More prolonged bursts, or regular, sustained spike discharges, were not seen in immature cortex. Unit activity in immature cortex often was synchronous with muscular twitches, similar to the findings in subcortical fibres.

Most of the recordings in this investigation were obtained during sleep; the reason for this is that records in waking kittens tend to be obscured by movement artefact. A few units were investigated after arousal of the animals, but these showed no obvious changes in discharge patterns from those found in sleep. In kittens less than 10 days old it was at times difficult to be certain whether an animal was asleep or awake, since the electroencephalogram patterns associated with sleep and waking in adults were as yet absent.

The present observations indicate that cerebral cortex in the areas investigated is not in a functioning state at the time of birth. Impulses in afferent fibre tracts are reaching cortex at this stage of development, but cortical neurones are not activated by the afferent volleys. The earliest activity in cortical neurones shows little of the

complexity seen in adult cerebral cortex. It consists of discharges in brief bursts which appear to occur synchronously in large neuronal populations, and which correlate with muscular twitches in the animals.

Polarized Light Responses from Crab Retinula Cells

LIKE many other arthropods, crabs can orientate themselves to plane polarized light[1], and it has been shown that single retinula cells of the fly can respond differentially to the plane of polarization[2–4].

Evidence from vertebrate rods indicates that the photopigment chromophore is strongly dichroic and highly orientated only in the plane parallel to the rod disk membrane[5]. It is an attractive possibility that the pigment chromophores in the arthropod rhabdom are arranged both parallel to the membrane and in line with the axis of the regularly arranged tubules which make up the rhabdom structure. This would provide a polarization analyser, in contrast to the vertebrate arrangement.

The decapod Crustacea provide an opportunity for investigating this conjecture in that they have only two alignments of rhabdom tubules at right angles to one another, in a regular array across the eye[6–8].

Freshly excised eyes of *Carcinus maenas* were mounted in sea water in a small chamber, looking out through a glass coverslip. An optical perimeter allowed a small bright source (0·3° at the eye) to be located on the visual axis of a cell. Care was taken to see that the emerging light was at this stage non-polarized. A 'Polaroid' sheet that could be rotated through 360° in 15° steps, and an interchangeable set of neutral density filters, were interposed in the beam.

The procedure was to locate a retinula cell through a hole in the cornea using conventional intracellular microelectrode techniques, find its optical axis, and rotate the 'Polaroid' through successive positions in between repetitive 200 msec light flashes. This produces a differential response with a minimum sensitivity at 'Polaroid' positions 2 and 14 in the example shown (Fig. 1*a*). Adaptation during a series of flashes is usually negligible as can be judged by the symmetry of the responses. Measurements are taken from the 'Polaroid' positions at minimum sensitivity where adaptation is least. The angle of the 'Polaroid' for maximum stimulation relative to a particular row of ommatidial facets in the region of interest is noted so that measurements on different eyes can be related.

Relative to this co-ordinate, cells fall into two well-defined groups with maximal polarization-sensitivities 90° apart (Fig. 1*d*).

Should recording conditions be stable enough, it is possible to plot the intensity-response curve (Fig. 1*b*), and the response to constant flash at different angles to the optical axis (Fig. 1*c*). The equivalent angular sensitivity curve is then calculated[9], and in this case, when corrected for refraction and a scale error of the stimulator, the acceptance angle at half sensitivity in the vertical plane for the animal is 2·5°. This is representative for the few accurate measurements made.

Likewise, data in Fig. 1*b* can be used to measure the actual sensitivity to light polarized in different planes. Fig. 1*a* represents a 7·7-fold change in sensitivity between response extremes: it is equivalent to a change in light intensity from 100 per cent to 13 per cent, or 0·89 log unit. This would seem to be representative for the few cells accurately measured so far. It contrasts with a change of about 0·3 log unit in the fly[3] and 0·1–0·7 (mean 0·37) in the locust[10], where all the cells appear to respond to some extent. Other data from the fly[4] are more difficult to interpret, especially as only half the cells are claimed to be selective and yet no figures for the lower limit of detectability are given. A conservative estimate of 0·05 log unit would be appropriate in the present work, which would be difficult to distinguish from Fresnel artefacts. Cells differ considerably in their intensity-response curves so that it is necessary to determine each individually if accurate comparisons are to be made or response saturation avoided. The large differences in polarization sensitivity between cells and between animals presumably reflect a greater degree of alignment of rhabdom tubules or of pigment within them.

Neither the polarization plane for maximum response nor the actual sensitivity to polarized light changes measurably on altering the angle of incident light either in crab or locust, although this can necessarily be varied only over a small range because of narrowness of receptive field. For the locust, removal of the experimental chamber glass window does not affect the response, and simultaneous recordings from two electrodes in one ommatidium on one occasion showed that two different cells had peak responses at polarization planes 60° apart. In this case the rhabdom is the only structure in the optical path which is not shared by both cells. This evidence militates against the alternative that the polarization responses reported here are artefacts due to extrinsic Fresnel reflexion effects at some interface, producing intensity differences on the receptors. Such effects would in any event be much too small to explain the response magnitudes observed unless multiple reflexions were involved, and these are certainly not present here.

Taken with this evidence, the finding in the crab of two groups of cell with maximal polarization sensitivities at right angles to one another (Fig. 1*d*) reinforces the belief

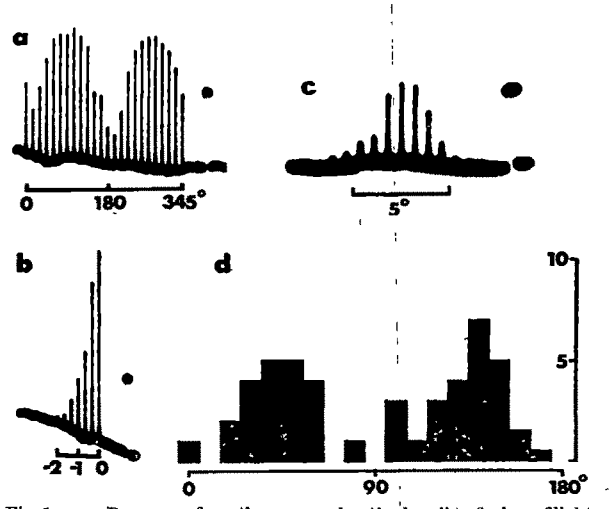

Fig. 1. *a–c*, Responses from the same crab retinula cell to flashes of light. Calibration pulses are 10mV and interflash intervals 2·5 sec throughout. (*a*) Response to flashes at different planes of polarization of incident light. A 'Polaroid' sheet is rotated 15° between flashes. (*b*) Approximate response-log intensity curve plotted directly from the response by removing neutral density filters from the beam From the right, successive log attenuations are 0, 0·3, 0·7, 1·0, 1·3, 1·7, 2·0 (*c*) Response to the light source attenuated by 0·7 log unit when moved across the receptive field in equal 0·7° steps (corrected, see text) (*d*) Plane of polarization relative to the eye (abscissa), against numbers of cells with each orientation of maximal sensitivity (ordinate) Forty-seven cells

that the photopigment orientated in the rhabdom tubules constitutes the polarization analyser. This view is strengthened by recent work on selective adaptation of *Octopus* electroretinogram with polarized light[11].

Dissociation between Antidiuretic and Vasopressor Activity in Rat Posterior Pituitaries on Incubation *in vitro*

IN an investigation designed to investigate whether the release of vasopressin (ADH) from rat posterior pituitaries *in vitro* would be a reliable index of the discharge of this hormone *in vivo*, a dissociation between antidiuretic and vasopressor activity was found on incubation in the posterior lobe as well as in the medium.

Male white rats weighing from 170 to 270 g were anaesthetized with an intraperitoneal injection of 4·25 mg of sodium pentobarbitone per 100 g. After 30 min the animals were decapitated and the posterior pituitary was quickly removed and weighed to the nearest 0·05 mg on a torsion balance. The gland was either submerged in 0·1 ml. of 0·1 N hydrochloric acid for extraction of peptide material or it was placed in flasks containing 2 ml. of Krebs–Ringer-bicarbonate glucose (200 mg per cent) at 37° C and shaken for 1 h in a Dubnoff metabolic shaker under 95 per cent oxygen and 5 per cent carbon dioxide. At the end of the incubation the posterior pituitary was removed and extracted in the same way as the fresh posterior lobes. Glands were ground with a glass rod and were diluted with saline after complete destruction before assay. The material present in the incubation medium and in the posterior lobes was immediately assayed for its antidiuretic and its vasopressor activities.

Antidiuretic potency was determined in the female rat anaesthetized with alcohol[1] and the vasopressor potency was measured in the male rat pretreated with dibenzyline and anaesthetized with urethane[2]. A 4·2 dose assay was carried out using purified lysine vasopressin (Organon, *N.V.*, Oss, Holland) as the standard.

Table 1 summarizes the results. The amount of antidiuretic and vasopressor activity before incubation varies considerably from gland to gland. The two activities did not, however, differ significantly. The data are in agreement with those of others[3–5]. After 1 h incubation, the posterior lobe had lost nearly all its antidiuretic activity, while the vasopressor activity was reduced only slightly. The antidiuretic activity seemed to have been released into the incubation medium, as the amount present in the medium did not differ significantly from that which had disappeared from the posterior lobe during incubation. Accordingly, incubation of the posterior lobe gave rise to a dissociation between the two activities of the posterior lobe principle.

Table 1. ANTIDIURETIC AND VASOPRESSOR POTENCY OF POSTERIOR PITUITARY TISSUE AND OF INCUBATION MEDIUM

	Posterior pituitary extract		
	Before incubation	After 1 h incubation	Incubation medium
Antidiuretic activity	1·29* ± 0·49†	0·03 ± 0·01 $P < 0·01$	1·13 ± 0·19 $P < 0·01$
Vasopressor activity	0·53 ± 0·10	0·62 ± 0·28	0·04 ± 0·01

* U/mg fresh posterior pituitary.
† Mean of six assays ± standard error of the mean.

Since the isolation, structure-analysis and synthesis of vasopressin by Du Vigneaud *et al.*, it has been taken for granted that this peptide (with a vasopressor/antidiuretic activity ratio of unity) is the principle formed and stored in the supraoptic-neurohypophysial system. Recent data from Sachs and Takabatake[6] suggest, however, that vasopressin may be formed in the form of a precursor which is transformed into the active principle on transportation to the posterior lobe.

The present experiments reveal that at least two principles are present in the posterior lobe on incubation, one with mainly vasopressor and one with mainly antidiuretic activity. It may be that changes have taken place under the present artificial conditions with the consequent formation of two factors with different diffusion characteristics. It is also possible that the precursor molecule is transformed into peptides of different biological activities. This may occur not only *in vitro* but also *in vivo*, since Hild and Zetler[7] showed that the antidiuretic activity of the hypothalamus was lost before the vasopressor activity when dogs were dehydrated for several days.

IMMUNOLOGY

Suppression of Homograft Immunity in Chickens grafted *in ovo* with Allogeneic Thymus

NO convincing evidence exists which demonstrates that mammalian thymus cells can directly express their immunological activity. It has been assumed, therefore, that the immunological role of the thymus is an indirect one, that is, that it supplies the 'executive' part of the immune machinery of the body with cells the replication of which may well be required to establish normal immune function. Nevertheless, the relationship of thymus cells to the plasma cells as well as to the population of small lymphocytes (which has been considered to be linked with several immune manifestations including tolerance[1,2]) is still obscure. A similar concept could be applied to the immunological function of the thymus in birds. However, some observations made in chickens have suggested that cells derived from the thymus might be properly qualified to induce directly an immune response or at least to participate in it[3–7]. This report provides some evidence to show that the thymus is capable of inducing a state of tolerance to skin homograft in the chicken.

Non-inbred Rhode Island Red embryos and chickens of unknown blood group genotype and parentage were used in this investigation. Thymic lobes were aseptically removed from 8-week-old donor animals and cut into pieces varying in size from 2 × 3 mm to 2 × 4 mm. One piece of thymus was placed on the ectodermal layer of the chorioallantoic membrane of 12-day-old embryos. The method of implantation was essentially that developed by Ballantyne[8]. Grafted embryos were divided into four groups. One group was killed on the fifteenth, another

on the eighteenth, and the third group on the twenty-first day of incubation. Thymus grafts, chorioallantoic membrane and spleen were taken for histological examination. The fourth group of embryos receiving grafts was allowed to hatch, and 3-week-old chickens from this group were used as recipients of skin homografts. For this purpose, the same chicken which served previously as the thymus donor was now used as the skin donor. Skin grafts 1·5 mm × 1·5 mm were taken from the thorax of the donor and transplanted to the corresponding place on the chest of recipient chickens. Six days after transplantation the adhesive dressing was removed and daily observations made of the skin grafts. The intensity of the reaction was graded grossly. No attempts were made to find haemagglutinins for donor red blood cells in the sera of chickens grafted *in ovo* with thymus.

Three days after transplantation on chorioallantoic membrane, histological examination of thymus grafts revealed various degrees of vascularization. There were no signs of necrosis, and the cellular architecture of the implants was well preserved; however, grafts taken from 18- and 21-day-old embryos showed cell depletion of varying intensity.

In 15-day-old grafted embryos the spleen sinuses were filled with mononuclear cells of different types, whereas such cells were rare in the sinuses of non-grafted embryos (Table 1). Occasionally, some of these cells exhibited the earliest characteristics assigned to the plasmacellular elements. Six days after grafting, necrotic foci surrounded by multi-nuclear giant cells appeared in the spleen. No necrotic lesions were observed in the control embryos. In a number of spleen sections, a well-defined empty reticular structure was seen 9 days after transplantation. At that time of incubation (21 days) the spleen of embryos receiving grafts was larger than in the intact controls (Table 2).

Table 1. HISTOLOGICAL FINDINGS IN SPLEEN AND CHORIOALLANTOIC MEMBRANE OF 15–21-DAY-OLD EMBRYOS GRAFTED WITH THYMUS

Group	Spleen			Chorioallantoic membrane	
	Mononuclear cells in sinuses	Empty reticulum	Necrotic lesions	Cellular infiltration	Necrotic lesions
Control	±	0	0	0	0
Grafted	+++	++	+++	+++	++

Table 2. SPLEEN WEIGHT OF EMBRYOS GRAFTED WITH ALLOGENEIC THYMUS

Group	Spleen weight (mg)*		
	15-day-old	18-day-old	21-day-old
Control	11·2	10·2	13·2
Grafted	10·6	10·9	31·0

* Mean represented by five embryos.

Table 3. SKIN HOMOGRAFT REJECTION IN 3-WEEK-OLD CHICKENS GRAFTED *in ovo* WITH ALLOGENEIC THYMUS

Group	Gross rejection at					
	6 days		9 days		18 days	
	Not rejected	Rejected	Not rejected	Rejected	Not rejected	Rejected
Control	0	14				
Grafted	13	0	10	3	4	9

Extensive cell infiltration of the chorioallantoic membrane was observed in embryos receiving grafts (Table 1). Cell aggregates consisted mainly of mononuclear cells, medium and large lymphocytes, a few small lymphocytes, reticulocytes, blasts and some unidentified cells. This cell population showed a marked deficiency in ribonucleic acid. Cellular formations resembling the Hassall's corpuscles in the thymus were noted in the chorioallantoic membrane. Six and nine days after transplantation necrotic lesions occurred in the chorioallantoic tissue.

The results are presented in Table 3 of skin homograft rejection in 3-week-old chickens. All chickens which were not grafted at the embryo stage with thymus material rejected skin homografts in a manner indistinguishable from the rejection observed in an additional group of control chickens hatched from sham-operated eggs. The rejection was complete 6 days after grafting. At that time, the skin grafts in chickens which had been implanted *in ovo* with thymus material were in excellent condition. Four of thirteen chickens of this group showed no signs of homograft rejection even at 18 days.

Our observations indicate that implantation of allogeneic thymus on the chorioallantoic membrane of 12-day-old embryos induces a graft-versus-host reaction, thus providing further evidence for the immunological competence of chicken thymus cells. Splenomegaly is presumably produced by proliferating host cells as well as by colonization of the spleen with cells coming from the implant[9]. The same could be said for aggregates of cells in chorioallantoic membrane[10,11].

Another important feature of this investigation is the induction of partial tolerance to skin homograft following *in ovo* transplantation of thymus from adult chicken. This state of tolerance is probably due to the lymphocytes of a number of embryos being immunologically immature at the time of grafting[12]—assuming that skin and thymus cells share common isoantigens. It can also be argued that cells deriving from the thymus graft are 'accepted' by recipient animals, and that such cells continue to multiply and differentiate in lymphoid tissues of the host resulting in partial suppression of homograft immunity. Both explanations imply the persistence of antigen in the host[13]—although the second assumption assigns a more functional role to donor thymus cells in the initiation and maintenance of tolerance. The latter seems acceptable when the part played by thymus-dependent lymphoid tissue in delayed hypersensitive responses of the chicken is taken into account[14–17].

Anti-ribonucleic Acid Factors in the Sera of Germ-free Animals

WHEN an animal is subjected to prolonged immunization with ribosomes (of whatever origin), its serum becomes progressively endowed with NG I antibodies*, which specifically precipitate various types of RNA and all the synthetic polyribonucleotides so far tested[1,2,4]. On the other hand, these sera and the sera of animals not immunized against ribosomes both contain NG II globulins[3]: these factors precipitate poly-I and poly-U only; however, the reaction is specifically inhibited by various RNAs (and by either poly-A or poly-C) but not by DNA. We have reason to believe that NG II factors in equine serum are antibodies which belong to the 7*S* globulin

* NG, anti-nucleic acid globulins.

fraction recently described by Sandor *et al.*[5]. However, we have previously shown that the sera of animals not immunized against ribosomes contain these factors in amounts of from ten to twenty times less than those found in immunized animals[3].

We were faced with the question of whether the presence of NG II in the sera of animals not immunized by ribosomes represents a response to an exogenous stimulus, that is, to ribosomes of bacterial origin.

To answer this, we undertook a comparative investigation of the sera of germ-free and conventional animals

The germ-free animals were Wistar rats descended from rats received from the Lobund Institute in June 1960. The control rats were also from this source.

The polyribonucleotides, obtained from Miles Chemical Co., were re-purified and the fraction containing products of higher molecular weight used. The RNA was a ribosomal RNA prepared from *Escherichia coli K* 12. Precipitation reactions, either in serum or in 0·14 M sodium chloride, 0 005 M *tris*, at *p*H 7·4, and the analysis of the precipitates were carried out by methods already described[6].

In the first series of experiments, immunological reactions were carried out with the sera of germ-free and conventional animals. The results are shown in Table 1 (each mean value represents three to twelve animals).

(*a*) Sera from either conventional or germ-free rats precipitated the poly-I. The age of the rat made no difference to the percentage of poly-I precipitated.

(*b*) For the same dose of poly-I, the quantities of conventional serum proteins present in the precipitate increased between the first and third months, but did not vary noticeably thereafter.

(*c*) For sera of both germ-free and conventional animals, the quantity of protein present in the precipitates increased with the quantity of poly-I added.

(*d*) This reaction has the same specificity character as has been observed in rabbit, goat, horse and human sera[3,7], as the precipitation is inhibited by RNA and by both poly-A and poly-C, but not by DNA or poly-U.

It is possible to utilize, instead of the sera, the euglobulin fractions obtained during dialysis against a medium of low ionic strength at *p*H 6·3 (refs. 4 and 7). These fractions contained all the NG II factors. The quantity of euglobulins present in conventional sera was 10–90 per cent higher, depending on age, than that present in germ-free sera. For conventional rats, the concentration increased continuously with age; in the case of germ-free sera, the concentration remained unchanged after the third month (Table 2).

Furthermore, the results listed in Table 3 (mean values obtained for three to fourteen animals) indicate that the percentage of poly-I precipitated increased regularly with the decrease in the quantity of poly-I added. The percentage of poly-I precipitated reached about 15 per cent for a ratio "euglobulin added/poly-I added" greater than 40, whereas the ratio "protein precipitated/poly-I precipitated" stayed about unity.

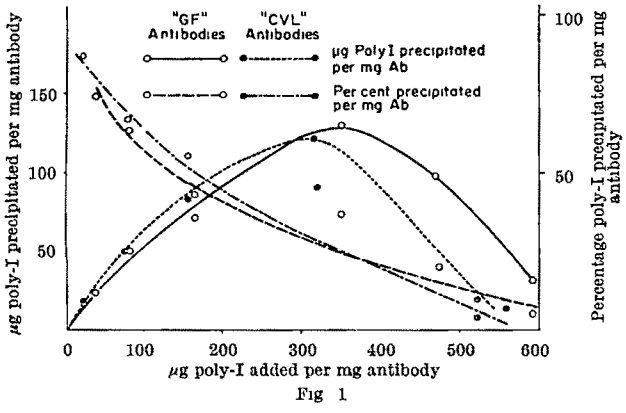

Fig 1

These results show that an important proportion of the euglobulins did not represent NG II factors. It was possible to purify and to concentrate NG II by a previously described method[3,4]: dissociation of the specific precipitate obtained from the euglobulins by 1 M magnesium chloride or 2 M lithium chloride. The proteins went into solution and behaved as NG II factors, similar to those obtained from the sera of animals of other species.

In one experiment, we prepared NG II from two euglobulin pools obtained from conventional (thirty-two rats) or germ-free (twenty-eight rats) sera. In the case of conventional rats, 15 ml. of serum produced 21 mg of euglobulins and this in turn gave 2·2 mg of NG II. Thus about 140 μg NG II was produced per ml. of serum. In the case of germ-free rats, 12 ml. of serum yielded 9 mg of euglobulin, which in turn gave 0·8 mg of NG II, that is, 66 μg/ml. of serum.

The conventional or germ-free factors showed an identical activity (Fig. 1). Moreover, the precipitation curves exhibited the usual aspects of immunological precipitation, and characteristic zones of equivalence and of inhibition in excess of antigen were present.

Finally, poly-I precipitation, in both conventional and germ-free NG II, was inhibited by poly-A, poly-C and RNA, but not by poly-U or DNA.

A second purification by dissociation of the new precipitates yielded about 50 per cent values. After a third purification, this quantity remained unchanged.

The results presented here suggest a physiological explanation of the synthesis of NG II factors. Accordingly, these factors result from a normal globulin synthesis which could be due to autologous immunization (for example, by the animal's own ribosomes liberated as a result of endogenous cytolysis). On the other hand, it is also possible that the properties of NG II reflect an intrinsic quality of certain normally synthesized globulins.

The precipitation of poly-I is, indeed, only an indication of the presence of factors which have the biologically important property of combining with RNA to give soluble complexes[3]. It is possible that, in certain cases, such a combination could maintain, or even reinforce, the functional value of the RNAs. Although auto-antibodies are usually referred to as negative (unfavourable) because of their pathological consequences, we suggest, on the basis of our results, that some auto-antibodies exist as positive (favourable) elements in the organism, which are synthesized by it and necessary to it.

RADIOBIOLOGY

Photosynthesis and Uptake of Strontium-85 in Freshwater Plankton

AMONG the radioisotopes which are assimilated differentially in light and dark by phytoplankton or macrophytes are phosphorus-32[1], zinc-65[2], strontium-89 and 90[3], molybdenum-99[4] and caesium-137[5]. This communication considers this effect for strontium-85 in relation to primary productivity.

Rice's work with radioactive strontium[3] indicated assimilation by twelve species of marine algae (mostly planktonic) to be primarily by ion exchange, but at different rates for different species. Cells killed by acid or heat took up strontium by adsorption or exchange, and the process was complete within minutes. In a light–dark experiment living cells kept in the dark for 72 h did not concentrate strontium to significantly greater levels than killed cells, but illuminated cells accumulated strontium with increasing population size and in proportion to the rate of cell division. Most of this radioactivity was exchangeable.

Fig. 1 shows light and dark uptake of strontium-85 by organisms in water obtained from a depth of 2 ft. in Melton Hill Lake, Oak Ridge, Tennessee, on August 26, 1964, and incubated in a controlled environment

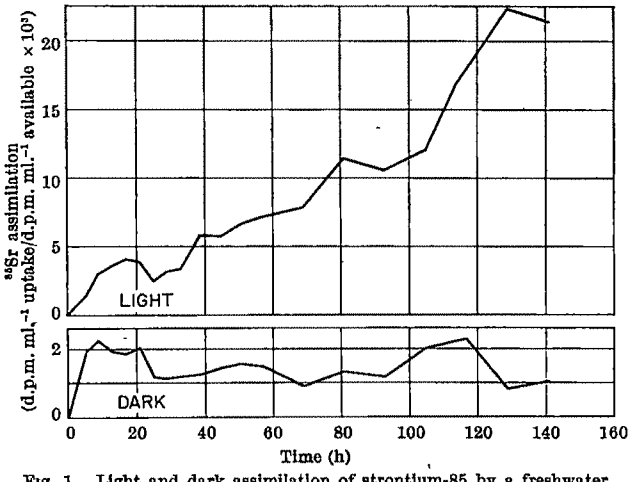

Fig. 1. Light and dark assimilation of strontium-85 by a freshwater plankton aggregation as a function of time

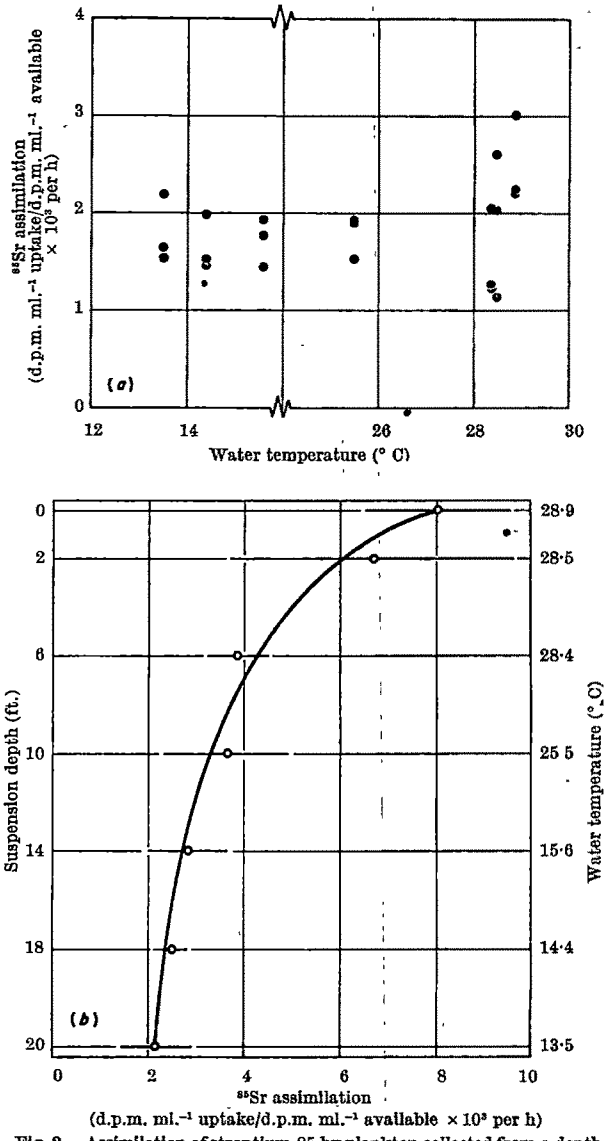

Fig. 2. Assimilation of strontium-85 by plankton collected from a depth of 8 ft. in Melton Hill Lake on July 29, 1964, and suspended *in situ* for 6 h at various depths. Initial phytoplankton concentration was 4·1 × 10^3 cells/ml. Principal genera were *Synedra* and *Navicula*; minor species were from *Achnanthes*, *Chlamydomonas*, *Oocystis*, *Scenedesmus*, *Peridinium* and *Euglena*. (*a*) Assimilation in dark as a function of temperature (three replications at each suspension depth). (*b*) Assimilation in light as a function of suspension depth (means of three replications, with two standard errors on either side of each mean)

chamber (temperature about 25° C, light about 1,000 ft.-candles, photoperiod 12 h). Initial phytoplankton concentration was 36·6 × 10^3 cells/ml., and principal forms were *Achnanthes*, *Navicula*, *Synedra* and an unidentified green alga with lesser concentrations of *Chlamydomonas*, *Chlorella*, *Oocystis*, *Peridinium*, *Scenedesmus* and *Synura*. Initial uptake of strontium-85 proceeded rapidly in both light and dark, but assimilation in light became greater after 6 h. Both light and dark samples showed a decrease in cell radioactivity for about 24 h, after which the dark material remained approximately constant while the illuminated samples showed a linear increase with time.

The results in Fig. 1 are typical of our experience with natural populations from Melton Hill Lake. Not all species in a mixed population may be responsible, however, as is shown by an experiment with cultured *Spongiochloris excentrica* Starr, which gave no differential assimilation in light and dark during 48 h.

To relate the results of Fig. 1 to light and temperature levels, a series of 6-h field experiments were performed *in situ* in Melton Hill Lake. Aliquots of a composite sample

of natural material from the lake were suspended in dark and light '*BOD*' bottles at different levels in the water column. The lake was thermally stratified during the summer, when this work was performed, providing a vertical gradient of ambient temperatures. Assimilation under dark conditions in a typical experiment is given as a function of temperature in Fig. 2*a*. The data indicate no change in strontium-85 uptake over a temperature range of 13·5°–28·5° C; at 28·9° C, however, uptake was significantly greater. This was the surface water temperature and dark bottles suspended at this level were exposed to fairly direct sunlight which may have caused internal heating above ambient temperature. From Fig. 2*a* and similar data from other experiments it is concluded that strontium-85 assimilation by natural plankton material is independent of temperature except possibly at abnormally high temperatures. Thus, metabolism does not appear to play a significant part in the uptake of this radioisotope. On the other hand, assimilation in light is dependent on light intensity. This is shown in Fig. 2*b*, where the vertical profile of strontium-85 uptake shows an exponential decrease with depth which must be related to the pattern of light extinction since temperature is not a factor.

Data such as those of Fig. 2*b* raise the possibility that strontium-85 uptake may be related to primary productivity. If it were possible to quantify such a relationship over a wide range of organisms and environments, this radionuclide could prove useful in the estimation of aquatic production because assay of its gamma-radioactivity is easy compared with carbon-14. Preliminary comparisons of Melton Hill Lake productivity as determined by the oxygen method[6] and by strontium-85 assimilation gave results typified by Fig. 3, which shows the same experiment as Fig. 2. As shown, a linear relation exists between net oxygen production and strontium-85 uptake at low and intermediate light intensities (suspension depths of 6 ft. and below), but at high light levels (0 and 2 ft. suspensions) oxygen production was inhibited while strontium-85 accumulation continued to increase. Photosynthetic inhibition under high illumination is commonly observed when production is determined by oxygen and carbon methods. The continued increase of strontium-85 assimilation with increased light (Fig. 3) has two possible explanations: (i) accumulation of the radioisotope is related to photosynthesis and photoinhibition of the latter is therefore an artefact of the usual methods of measuring productivity, or (ii) uptake is dependent on light but the mechanism is unrelated to photosynthesis.

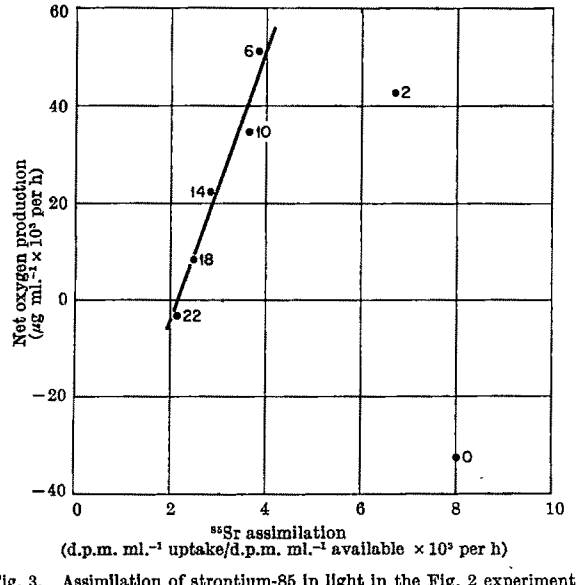

Fig. 3. Assimilation of strontium-85 in light in the Fig. 2 experiment as a function of net oxygen production (dissolved oxygen determined by the Pomeroy–Kirschman–Alsterburg modification of the Winkler method). Suspension depths in ft. are indicated beside each data point

The first possibility ostensibly requires both decreased oxygen production and decreased carbon assimilation since photoinhibition has been amply documented by both carbon and oxygen methods. However, recent evidence indicates that phytoplankton excrete significant quantities of photoassimilate into the medium as dissolved organic matter[7]. If this process was accelerated under intense illumination while assimilated strontium-85 were retained, then a significant lowering of the photosynthetic quotient (oxygen produced/carbon dioxide assimilated) in high light, involving both reduced oxygen output and increased carbon uptake with subsequent elimination, could explain the results in Fig. 3.

The second possibility suggests several alternative mechanisms. First, Rice[3] has indicated that strontium-85 uptake occurs by adsorption and exchange. The former process is a function of surface area so that acceleration of cell division by light[8] could produce increased uptake of the radioisotope even though biomass production was photoinhibited. Secondly, phytoplankton cells of many kinds contain light-sensitive organelles other than chloroplasts, such as stigmata and non-green chromatophores. Stigmata are usually thought to function in phototaxis and chromatophores in photon capture by accessory photosynthetic pigments, but it is conceivable that they may also in some way serve in the regulation of mineral metabolism. One or both of these mechanisms could explain how the assimilation of strontium-85 can be dependent on light yet independent of photosynthesis. There may be others to consider as well.

These conjectures indicate that new problems in primary production can be brought to light through investigations using radioisotopes, and that further work to establish the basis of differential light–dark assimilation of strontium-85 and other radionuclides may lead to additional insights and clarifications of productivity processes.

This work was supported by the U.S. Atomic Energy Commission under contract with the Union Carbide Corporation. We thank Dr. C. E. DePoe and Mr. N. A. Griffith for help with field work, and Dr. W. R. Herndon, who identified the green alga *Spongiochloris excentrica* Starr.

Effect of Ultra-violet Irradiation on Skin Collagen

Bottoms and Shuster[1] have shown that when hairless mouse skin is exposed to ultra-violet irradiation *in vitro* there is a decrease in the saline and citrate soluble collagen fractions; however, the insoluble collagen remains unchanged. At the same time, there is an increase in the toughness of the pelts. It was suggested that these effects of ultra-violet irradiation were due to increased cross-linkage between the collagen fibrils. In the experiments described here, we attempted to measure the degree of

cross-linkage of mouse skin and kangaroo tail tendon collagen before and after ultra-violet irradiation.

Harwell homozygous hairless albino mice were used throughout. Their necks were broken, and after a longitudinal incision made dorsally and ventrally the approximately equal half-pelts were removed to the paws, snout and tail. Subcutaneous fat was dissected away; the skin was dried with filter paper and weighed. One half-pelt was exposed to ultra-violet irradiation—the other half from the same mouse served as the control.

Salt-extracted, acetone-dehydrated kangaroo tail tendons[2] were given by the Research Station, Department of Agriculture and Stock, Warwick, Queensland, Australia. They were re-hydrated by soaking in distilled water for 24 h and in 0·9 per cent sodium chloride for a further 24 h. The tendons were then divided into two equal lengths, one half being exposed to ultra-violet irradiation and the other half of the same tendon being used as control.

The tendons and skins were placed in glass dishes, such that the epidermis of the skin was uppermost. In some experiments the tendons and skins were placed directly on the glass, in other experiments they were placed on a filter paper. The rims of the dishes were layered with silicone grease in order to make an airtight joint when they were covered by a quartz plate. The dishes containing the control tissues were covered with black paper to exclude the ultra-violet irradiation. Irradiation was carried out in a refrigerator so as to minimize bacterial decomposition, the dishes being placed at the bottom of a refrigerator at $-20°$ C. The ultra-violet source was from a medium pressure mercury arc (Hanovia lamp, ultra-violet *S*.220 arc tube type 504/4) and it was directed downwards from a point 24 in. above the pelts and tendons. Exposures were for 19 or 44 h. At the end of the exposure, the temperature adjacent to the tissues was never $> -4°$ C.

The tendons and pelts were weighed before and after irradiation. They were then treated in several changes of acetone, blotted and the residual acetone allowed to evaporate.

Comparison of the number of cross-links present in mouse skin and kangaroo tail tendon before and after irradiation was by load-extension and volume fraction measurements on the hydrothermally denatured materials, using experimental procedures already detailed[2,3] in conjunction with the Flory-Rehner equation[4]. Even if the absolute values of *Mc* and *C* are not given correctly by the calculation, the relative values for irradiated and unirradiated samples are certainly essentially correct.

The strip of mouse skin (6·0 × 0·5 cm) or piece of tendon (c. 15 cm in length) was soaked in distilled water overnight and then transferred to distilled water at 98° C for 30 sec. On removal its temperature was immediately reduced by quenching in cold water. For each experimental condition duplicate strips of mouse skin were prepared. All physical measurements were in distilled water at 65° ± 0·1° C after an equilibration period of 2 h at that temperature.

The results indicate that ultra-violet irradiation produces an increased molecular cross-linkage between the collagen fibrils both of hairless mouse skin and kangaroo tail tendon (*Mc* and *C*, Tables 1 and 2). The reduced capacity of the irradiated collagen to take up water (*V* in Tables 1 and 2) is presumably related to this increase in cross-linkage. The present results are in keeping with our previous observations that the saline and citrate soluble collagen fractions of hairless mouse skin are decreased by exposure to ultra-violet irradiation, because the more cross-linked collagens are insoluble in saline and citrate.

These findings may be pertinent to the changes which occur in the collagen of ageing human skin. There is a loss of collagen with age both in exposed and unexposed skin[5], but the collagen which remains is less soluble than in younger skin[6,7] and is more cross-linked[8]. It is now clear that ultra-violet irradiation *in vitro* produces collagens with properties resembling those found in ageing skin, which result from the production of intermolecular cross-links. The precise mechanism of this effect of ultra-violet irradiation will need further elucidation.

ENTOMOLOGY

Radiation Sterilization of Sugar-cane Leafhoppers of the Family Delphacidae

WE are at present investigating the possibility of eradicating sugar-cane leafhoppers of the genus *Perkinsiella* by the sterile male technique as suggested by Knipling[1]. Insects of this genus are economic pests, because they are the vectors of Fiji disease[2] of sugar-cane.

We have found that the fifth instar nymph is the most suitable stage to irradiate, and all irradiations mentioned here are those of fifth instars. These irradiations were effected by gamma rays from a cobalt-60 source.

With *Perkinsiella saccharicida* (Kirk) we obtain sterility at 3,500 (females) and 10,000 rads (males). At these dose-levels, adult longevity and mating behaviour are not significantly affected. Their sperm is motile and thus sterility is presumably caused by lethal mutations. A dose of 12,000 rads renders a percentage of the sperm inactive, but adult longevity and mating behaviour are

not sufficiently affected to prevent the use of this dose in a sterile eradication programme. A dose of 23,000 rads renders the sperm inactive, shortens adult longevity and adversely affects wing development.

In preliminary release experiments using normal fifth instars caged with irradiated fifth instars we have been able to reduce progeny production according to the ratio of sterile to fertile insects.

The results so far indicate that we have a large safety margin within which we can produce sterility, without significantly affecting sperm motility, mating behaviour or adult longevity.

BIOLOGY

Morphogenetic Effects of Acidic Glycoproteins on the Development of Sea Urchin Eggs

IT is known that certain chemical agents can influence the differentiation of the ectoderm and the entomesoderm in the larva of the sea urchin. Thus certain acidic organic derivatives which carry sulphonic groups tend to favour the differentiation of ectodermic structures (animalization). The animalizing activity of these agents increases with their affinity for proteins[1].

It was considered to be of interest to determine whether acidic proteins, such as glycoproteins, are also able to induce the animalization of larvae. This article reports some investigations of the effect of the glycoproteins of fraction VI of ox serum (prepared by the method of Cohn *et al.*[2]). This fraction contains concentrated acidic glycoproteins such as orosomucoid and α2-glycoprotein[3,4], and the acidity of these is linked with the presence of acetylneuraminic acid in their molecule.

Fertilized eggs of the sea urchin *Paracentrotus lividus* were cultivated in sea water containing from 2 to 1 mg/ml. of Cohn fraction VI (obtained from the Nutritional Biochemicals Corporation) and a sodic derivative of sulphadiazine (M/1,000). Each culture contained in the region of 1,000 eggs/ml.

The larvae which developed under these conditions showed the morphological characteristics of animalization and radialization. The animalized larvae, however, predominated in cultures containing 2 mg/ml. of fraction VI, and were hyperciliated blastulae corresponding to type 3/4 in Hörstadius's[5] classification. The radialized larvae predominated in cultures containing 1 mg/ml. of fraction VI; these showed a typical radial symmetry, a body elongated parallel to the animal–vegetal axis and a well-developed pre-oral lobe covered with long, movable cilia. The radialization exhibited an attenuated aspect of the animalization when eggs were treated with animalizing agents at a concentration slightly less than that necessary to induce animalization.

In the control cultures prepared with the complete lyophilized ox serum (2 mg/ml.), the pluteus developed normally. The larvae also showed a normal morphology with acetylneuraminic acid at the same concentration.

It has been known since 1892 (ref. 6) that lithium ions tend to favour the development of entomesodermic structures (vegetalization). Eggs cultivated in the presence of lithium chloride ($6{\cdot}5 \times 10^{-3}$ M and $3{\cdot}25 \times 10^{-3}$ M) and fraction VI material (2 and 1 mg/ml., respectively) produced larvae more strongly vegetalized than did those cultivated in the presence of lithium chloride only.

These experiments thus revealed two new activities: (1) the animalizing action of acidic glycoproteins of the fraction VI of ox serum; (2) the reinforcement of the vegetalizing effects of the lithium ions by such acidic glycoproteins.

In the animalized larvae, the differentiation of an ectodermic type extends to territories which, in a normal larva, would have formed entomesodermic structures. This phenomenon can be interpreted when it is considered that, in territories the differentiation of which is thus modified, the genes responsible for the ectodermic differentiation are derepressed.

Histones (basic proteins) are able to repress the activity of the genes[7]. According to Frenster[8], nuclear polyanions by combining with histones can derepress the activity of the genes

Acidic glycoproteins form compounds with histones[9]. I therefore suggest that, in these experiments, acidic glycoproteins, as well as polysulphonic derivatives, by combining with basic proteins 'derepress' the activity of the genes responsible for the differentiation of the ectodermic structures. This derepression can be observed at the level of the genes, at the time of passing on the genetic message, and at the level of the ribosomes when this genetic message is translated. Concerning the first sphere of activity, it will be recalled that a hormone of a glycoproteic nature, gonadotrophin, has been shown to be capable of stimulating the synthesis of RNA within the nucleus[10]. Regarding the second sphere of activity, the cytoplasm of the sea urchin egg contains basic proteins of the histone type associated with ribosomes[11].

The second result which was brought to light by these investigations is the reinforcement by the acidic glycoproteins of the vegetalizing action of lithium ions. This effect suggests an increase in permeability to the lithium ions; such a phenomenon could be attributed to a modification of the physicochemical properties of the cellular membrane, or to the carrier role of the glycoproteins at the time when the lithium ions penetrate into the cells.

Exposure of Cut Flowers to Ethylene in the Presence and Absence of Carbon Dioxide

FLOWERS produce ethylene[1,2], and ethylene in low concentration has a marked effect on development and senescence of the cut bloom[2]. With gas chromatography and flame ionization detection[3], it has been possible to examine critically the effect of exposure to a concentration of 0·05 p.p.m. ethylene on carnations over a range of temperature. The time interval between cutting and the first appearance of petal wilt can be readily determined.

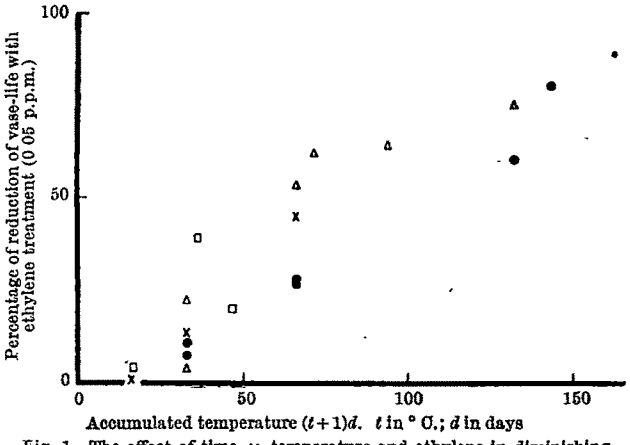

Fig. 1. The effect of time × temperature and ethylene in diminishing the vase-life of carnations. ×, 60° F (15·6° C); ●, 50° F (10·0° C); △, 40° F (4·4° C); □, 35° F (1·7° C)

The number of days between cessation of treatment and petal wilt is here termed 'vase-life' and has been determined at 16°–21° C.

The results of experiments in which carnation blooms were kept at different temperatures for various periods of time, in the presence and absence of ethylene at 0·05 p.p.m. concentration, in a continuous stream, have been brought together in Fig. 1. The percentage reduction in subsequent vase-life induced by exposure to ethylene has been plotted against accumulated temperature $(t+1)d$, that is, the product of the number of degrees difference between treatment temperature and the approximate freezing temperature (−1° C) and the number of days exposed to treatment.

Thus, an equivalent reduction of vase-life can be achieved by longer exposure at a lower temperature or shorter exposure at a higher temperature. It can be seen that there is a pronounced drift of the plotted points with increase of accumulated temperature.

Carbon dioxide at 5–10 per cent concentration was shown by Kidd and West[4] to delay the onset of the climacteric in apples, for the initiation of which it has been adduced that ethylene is responsible. Carbon dioxide in concentrations less than 10 per cent has also been shown to reduce the efficiency of ethylene in checking the elongation of pea seedlings[5].

We have observed a further inhibiting effect of carbon dioxide in that a concentration of the order of 5 per cent is sufficient to counteract the effect on the ageing of flowers of ethylene at 0·05 p.p.m. Carnation blooms, var. 'Red Sim', standing in water ('wet') or without water ('dry') were subjected to constant flows of air, air + 0·05 p.p.m. ethylene, 5 per cent carbon dioxide in air and 5 per cent carbon dioxide with 0·05 p.p.m. ethylene for 3 and 4 weeks at −0·4° C. The vase-lives recorded after treatment and removal to 16°–21° C are shown in Table 1.

A parallel experiment with cut narcissus blooms, var. 'Zurich', gave the results shown in Table 2.

Thus storage in 5 per cent carbon dioxide in the presence or absence of ethylene resulted in longer subsequent vase-life than storage in air, but storage in air with

added ethylene reduced life. Concentration of carbon dioxide of this order is unlikely to occur unless composition of the storage atmosphere is purposely controlled, for example, in so-called 'gas-packs'. Concentrations of ethylene of 0·05 p.p.m. with carbon dioxide less than 1 per cent may arise, as has been reported earlier[6], when cardboard containers are stacked in large bulk or when flowers are placed in proximity to a source of ethylene emanation, for example, ripening fruit, leakage of illuminating gas or when fog occurs in built-up areas.

Prevention of Ethylene Injury to Carnations by Low Concentrations of Carbon Dioxide

THE finding that the reduction of the life of carnations (that is, the time interval between cutting and first appearance of petal wilt) which results from exposure to 0·05 p.p.m. ethylene is completely counteracted by the addition of 5 per cent carbon dioxide to the atmosphere[1] raises the question of what is the threshold concentration of carbon dioxide for achieving the effect.

The threshold concentration of ethylene which will produce a significant reduction of life of the cut carnation bloom has not been determined. A concentration of 0·05–0·07 p.p.m. was, however, chosen as one which may occur under conditions of normal handling of cut flowers[2], and is also within the lower limit for accurate determination, in which gas chromatography and flame ionization detection are used[3]. Carnations were kept in an air stream of 20 l./h with or without ethylene and with a range of concentrations of carbon dioxide from 0·1 per cent (the amount present in the emergent stream without addition of the gas) up to a maximum concentration of 2·2 per cent when carbon dioxide was added. The requisite atmosphere was passed through a polythene film envelope enclosing the flowers standing in water with 0·003 per cent silver nitrate as bactericide. Treatments for 2 and 4 days were given at a temperature of 18·3° C and, after removal, observation of subsequent behaviour was made at 18·3° C in air at 60 per cent relative humidity. The results of

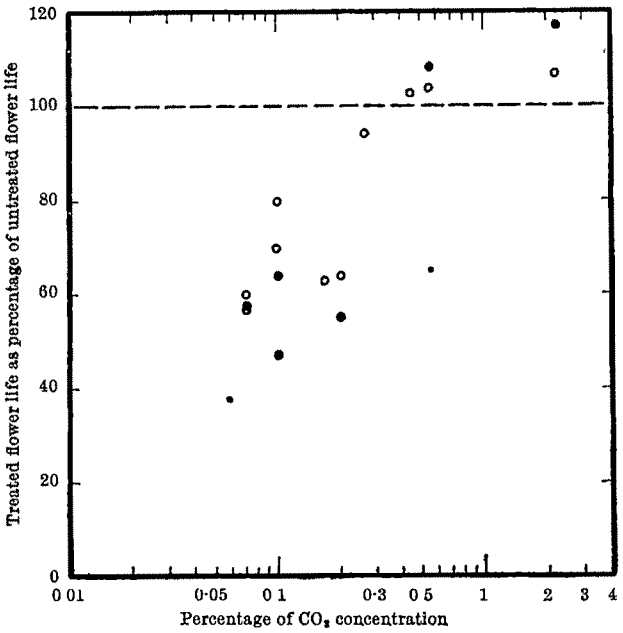

Fig. 1. Effectiveness of carbon dioxide in checking the reduction of life of cut carnation blooms when exposed to 0 05 p.p.m. ethylene; O, 2-day treatment; ●, 4-day treatment

two such experiments made on successive batches are given in Table 1.

Fig. 1 brings together the results of six experiments on carnations, in which different concentrations of carbon dioxide were used for 2- and 4-day treatment. For convenience, carbon dioxide concentration is plotted on a log scale. In one experiment the treatments were given on flowers not standing in water, but the responses to ethylene and carbon dioxide were unaltered.

It will be seen that, in the presence of ethylene (0·05 p.p.m.), the total life of the flowers was only reduced below that in ethylene-free air when carbon dioxide concentration was less than 0·35 per cent. Above this concentration the presence of carbon dioxide resulted in slightly increased life over that of flowers in an air stream with no detectable ethylene and about 0·1 per cent carbon dioxide. This increase in life with carbon dioxide in the presence of low concentrations of ethylene has been reported before[1].

It now seems evident that a relatively low concentration of carbon dioxide is sufficient to overcome the effect of ethylene at ordinary room temperature. Partial restriction of ventilation, which may result, for example, from close stacking of flower boxes, in which concentrations of 0·05 p.p.m. ethylene and 0·4 per cent carbon dioxide occur is not likely to cause reduction of life[2].

VIROLOGY

Outbreak of Influenza *A/equi*-2 in Switzerland

EQUINE influenza virus was first isolated in 1956 in Czechoslovakia[1]; this original strain was called *A/equi*-1. A different type (*A/equi*-2) was recognized in 1963 in the United States[2]. For a number of years the *A/equi*-1 virus was apparently the only type responsible for horse influenza in Europe[3,4].

At the middle of March 1965, an epidemic of a serious febrile respiratory disease in horses broke out and quickly spread to the whole of Switzerland. Investigations were carried out on conjunctival and nasal swabs and on lung and on blood specimens which had been collected in the Federal Army Remount Depot (EMPFA) in Berne and in a riding stable in Geneva.

Isolation assays were made by inoculation of the material into the amniotic and allantoic cavity of 11-day-old eggs. One out of twelve conjunctival and nasal swabs (No. 65-891, Berne) and one out of five lung specimens (No. 65-951, Geneva) yielded an haemagglutinating agent. These two agents were identified as influenza *A/equi*-2 viruses by both haemagglutinating inhibition (HAI) and complement fixing (CF) tests. Acute and convalescent horse sera, which had been treated with potassium periodate to remove non-specific inhibitors, were used for identification by HAI tests[5]. The increase in antibody titre shown by convalescent sera was found to be almost identical when tests were carried out with the same number of HAI units of both isolates and of a reference strain (*A/equi*-2/New York/63) (Table 1). CF tests were carried out with specific *A/equi*-2 *V*-antisera prepared in guinea-pigs using the method of Henle *et al.*[6]. Both isolates (Nos. 65-891 and 65-951) reacted as influenza *A/equi*-2 viruses (Table 1).

Acute and convalescent sera of twenty-four horses were tested by HAI and CF tests at dilutions of 1 : 8 and higher. After all sera had been treated with potassium periodate, HAI tests were carried out with two haemagglutinating (HA) units of *A/equi*-1/Prague/56 crude allantoic fluid and with the same number of HA units of *A/equi*-2/New York/63 ether-treated allantoic fluid[7]. CF tests were performed at the same time with two CF units of an influenza *A* soluble antigen and with equivalent amounts of *A/equi*-1/Prague/56 and *A/equi*-2/New York/63 pure particular antigens prepared by the method of Lief and Henle[8]. Three units of complement were used, since horse sera are naturally slightly anti-complementary.

In both tests, only a fourfold or greater increase in antibody titre has been considered as significant. Results are summarized in Table 2. They clearly show the evidence of a recent infection with an influenza *A/equi*-2 virus in nineteen out of twenty-four horses by CF test and in all horses by HAI test. They confirm that the outbreak of respiratory disease in the Swiss horse population was caused by influenza *A/equi*-2.

A/equi-1/Prague/56 particular	1	0	1	2	5	1	1	7
A/equi-2/New York/63 particular	8	8	3	19	4	11	9	24

* Increase (4 = fourfold increase).

A significant increase in antibody titre against the *A/equi*-1 virus has been found in two horses by CF test and in seven by HAI test. Such results have been obtained only in animals which showed an increase of eightfold or greater in antibody titre against *A/equi*-2. This is more suggestive of a booster response to a common antigenic fraction in the *A/equi*-2 and in the *A/equi*-1 particles than of a recent or concomitant infection with the latter agent.

Our own unpublished investigations on horse sera collected in Switzerland in 1963 and 1964 show that at this time no animal had any antibody against influenza *A/equi*-2. It is therefore not surprising that the virus spread quickly and produced serious symptoms when introduced in such a receptive population.

Oncogenicity of Bovine Adenovirus Type 3 in Hamsters

THE prototype strain (*WBR* 1) of bovine adenovirus type 3 (ref. 1) is pathogenic for colostrum-deprived calves[2], and serological evidence indicates that, in addition to bovine adenovirus types 1 and 2, this serotype is involved in natural outbreaks of respiratory disease in cattle[3]. It has now been shown that the *WBR* 1 strain can induce the formation of tumours in hamsters, a capacity shared by certain other adenoviruses including human types 3, 7, 12, 18 and 31 (refs. 4–8), the chick embryo lethal orphan (CELO) virus[9] and a number of simian adenoviruses[10].

Nine litters of Syrian hamsters were inoculated by various routes on the day of birth with different doses of virus (strain *WBR* 1) grown in primary bovine kidney (BK) cultures and, in a number of these animals, tumours later developed at the site of inoculation. These tumours were either of a relatively firm consistency, resembling tumours induced by other adenoviruses or, as the virus dose was increased, were of a cystic type which appeared more rapidly (see Table 1). The cysts were largely filled with blood, although they also contained nodules of firm tumour tissue. Neither type of primary tumour was progressive; the firm tumours did not appear to grow after reaching a size of approximately 2–3 cm but remained static, whereas the cystic types regressed within 10 days leaving small subcutaneous nodules. Primary tumours of the firm type were transplanted in weanling and adult hamsters; in all these animals growth of the transplant tumours was progressive. Hamsters inoculated with uninfected BK cells remained healthy and free from tumours.

Table 1. INDUCTION OF PRIMARY TUMOURS IN HAMSTERS WITH BOVINE ADENOVIRUS TYPE 3 (STRAIN *WBR* 1)

		Total 22/45		

s/c, Subcutaneous. i/t, Intrathoracic. i/c, Intracerebral. i/p, Intraperitoneal.
* Survivors 7 days after inoculation.

On histological examination[11] of fixed tissues, the firm tumours were seen to comprise sheets of polygonal cells with numerous mitotic figures interspersed with multinucleate giant cells, some with ten or more nuclei. The general appearance suggested an undifferentiated sarcoma, but origin from epithelial tissue could not be excluded. In the cysts, the wall contained foci of tumour cells and the histological appearance of the nodules resembled that of the firmer tumours.

Monolayer cultures of primary or transplant tumours were comprised of cells resembling the types seen in sections. Such cells grown *in vitro* were capable of inducing progressive tumours when inoculated into adult hamsters. Attempts to demonstrate infective virus in tumours or their cultured cells have been unsuccessful to date.

Sera collected at various intervals after the appearance of tumours were used in complement fixation tests with 10 per cent extracts of tumour tissues or with tissue culture medium containing infective homologous virus. Complement-fixing antibody to viral antigen could be demonstrated in all hamsters, often in high titre, but could not be shown in significant amounts in those with transplant tumours. These findings may account for the stasis or regression of the primary tumours and for the progression of the transplant tumours. Complement-fixing antibody to tumour antigen was detected in low titre in one hamster with a primary tumour but not in any of the other hamsters. Complement fixation tests for the presence of polyoma or *SV*40 antibodies in the sera, or for antigens in the tumours, yielded negative results[12]. Neutralizing antibodies to bovine adenovirus type 3 were demonstrated in the sera of a number of the hamsters bearing primary tumours.

Bovine adenovirus types 1 and 2 were not found to be oncogenic for hamsters within an observational period of 90 days[7], whereas the present experiments indicate that bovine adenovirus type 3 is the first non-primate adenovirus, other than the avian CELO virus, which can induce tumours in hamsters.

Fractionation of Partially Degraded Tobacco Mosaic Virus Ribonucleic Acid

IN the step-wise analysis of nucleotide sequence in tobacco mosaic virus ribonucleic acid (TMV–RNA)[1], occasional random splitting of internucleotide bonds results in the production of partially degraded molecules. These

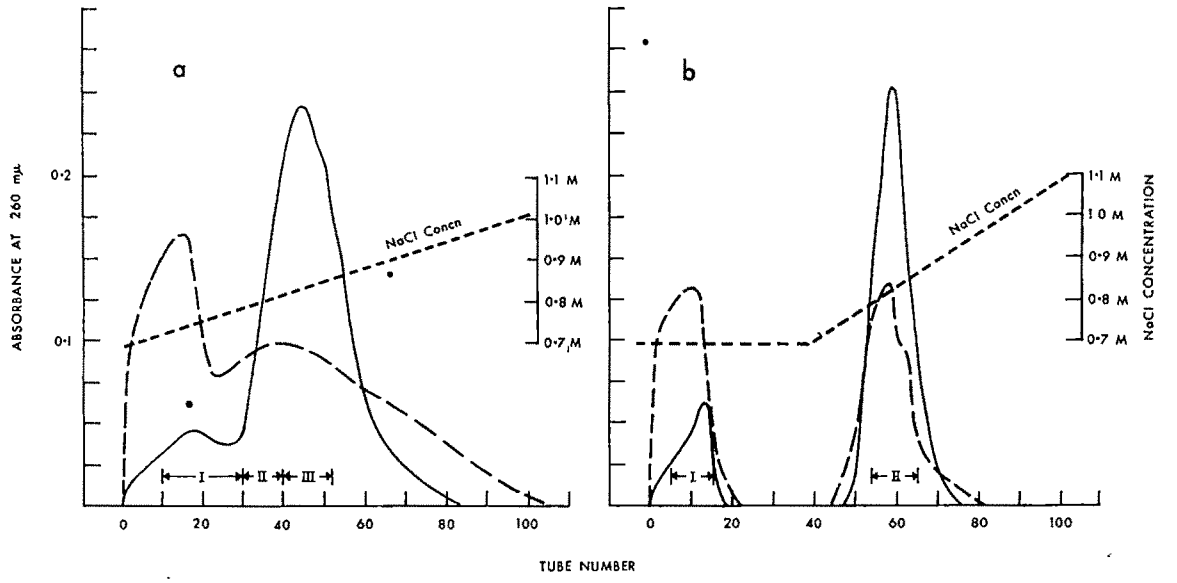

Fig. 1. Elution profiles of TMV–RNA from MAK columns. ——, Typical preparation of TMV–RNA. - - - -, Partially degraded TMV–RNA. (*a*) Gradient elution began immediately after RNA was loaded on to column. (*b*) Column was loaded and washed with about 100 ml. starting buffer before gradient elution was commenced

broken chains give rise to additional and, of course, false end-groups. In order that the sequence analysis be meaningful it is necessary that a method for the removal of broken chains be developed. We have looked into the possibility of separating undegraded from partially degraded TMV–RNA molecules by chromatography on methylated serum albumin–kieselguhr (MAK) columns[2]. Such a fractionation may also be of use in the reverse situation where it is desired to eliminate any intact molecules from a deliberately inactivated RNA preparation.

RNA was isolated from common strain TMV by a modified phenol technique[3]. As a source of partially degraded TMV–RNA we used both sonicated RNA and RNA recovered as a by-product from the isolation of TMV-protein[4]. Improvement, or otherwise, in the quality of the RNA as a result of fractionation was assessed on the basis of sedimentation behaviour and specific infectivity. Sedimentation velocity was determined at 4° C in 0·1 M phosphate buffer using ultra-violet optics. The infectivity of RNA samples (after reconstitution with TMV-protein[5]) was measured on *Nicotiana tabacum* L. var. Xanthi nc. by comparison with dilutions of a standard TMV preparation. Procedure for the MAK columns was as described by Mandell and Hershey[2], with the exception that the buffers were millimolar with respect to versene and 10 millimolar with respect to phosphate. The low solubility of phosphate in ethanol can be a problem during the recovery of the RNA from the column fractions.

Single-layer columns[6] with step-wise elution were used in the initial experiments to determine the optimum salt molarity at which the RNA should be applied and the sensitivity of the elution profile to variations in temperature and in the *p*H of the buffers. It was found that undegraded TMV–RNA is eluted from the column by 0·8 M sodium chloride, *p*H 6·7, at 2° C, but that, if either the *p*H of the buffer is 6·1 or the temperature is raised to 23° C, then 0·85–0·90 M sodium chloride is required to effect elution.

All further experiments were carried out using a three-layer column at 2°–4° C and a 250-ml. or 500-ml. linear salt gradient. Approximately 0·8 mg RNA was applied in 50 ml. 0·7 M sodium chloride and gradient elution started immediately. A typical elution profile for both normal RNA and partially degraded RNA is shown in Fig. 1*a*. The contents of the tubes were grouped into fractions as indicated and the RNA recovered by precipitation with ethanol. Recoveries from the column itself averaged 85 per cent of the starting material and precipitation of the RNA from the fractions was nearly quantitative. Sedimentation patterns and infectivity of the various fractions were compared with those of the unfractionated RNA.

In all columns we have run, the first fraction eluted appeared polydisperse in the ultracentrifuge and exhibited little, if any, infectivity (Table 1). Subsequent fractions showed varying amounts of the 31*S* component and considerable infectivity. Where the starting RNA was a partially degraded preparation it was possible to recover fractions from which, judging by their increased specific infectivity and sedimentation homogeneity in the ultracentrifuge, many of the degraded molecules had been removed. Where the original RNA was a good preparation (70–75 per cent homogeneous), then little improvement in quality was achieved. Flattening the elution gradient was without further benefit.

Our failure to remove completely the degraded molecules might have been due to tailing of the polydisperse, non-infectious material into the subsequent undegraded fractions. We examined this possibility by loading the RNA on to the column, washing with starting buffer

Table 1. ANALYSIS OF RNA FRACTIONS FROM MAK COLUMNS

Type of RNA	Unfractionated		Fraction I*		Fraction II*		Fraction III*	
	Infectivity†	Homogeneity‡	Infectivity	Homogeneity	Infectivity	Homogeneity	Infectivity	Homogeneity
Normal§	60	60	8	Polydisperse	59	66	63	71
Normal§	76	76	3	,,	77	71	91	82
Partially degraded§	21	28	0	,,	—	—	38	50
Normal‖	76	76	4	,,	80	83	—	—
Partially degraded‖	29	29	0	,,	53	53	—	—

* Fractions were obtained by pooling the contents of tubes as shown grouped in Fig. 1.
† Infectivity refers to the percentage of the RNA which reconstitutes with protein to form infectious virus.
‡ Percentage of the RNA which sediments as a homogeneous 31*S* component.
§ Elution pattern of type shown in Fig. 1*a*.
‖ Elution pattern of type shown in Fig. 1*b*.

until the absorbance at 260 mμ of the eluate returned to the base line and then beginning the gradient elution. Elution profiles for this type of procedure are shown in Fig. 1*b*. It can be seen, however (Table 1), that even with this variation not all the partially degraded molecules were eliminated from the RNA preparation.

It would seem, then, that it is possible by fractionation of MAK columns to remove many of the degraded molecules from a partially degraded TMV–RNA preparation. However, the efficiency with which this has been achieved is not so high as might have been expected, in view of the established resolving power of MAK-columns for other systems[7,8]. It is possible that greater resolution is obtained on the column itself but that, during the process of recovery of the RNA from the fractions, some degradation has taken place, thus cancelling some of the improvement in quality which might otherwise have been apparent.

We thank Miss F. Putney and Dr. H. K. Schachman for the sedimentation data, Mrs. B. Singer for infectivity assays and Dr. H. Fraenkel-Conrat for his continued interest.

AGRICULTURE

Influence of Seed Source on the Date of Ear Emergence in Bread Wheat

THE growth of grain crops may in some cases be influenced by the conditions under which the crop which produced the seed was grown. Among the characters affected have been yield[1] and winter hardiness[2] of winter wheat, and yield of spring wheat[3], while similar differences have been reported in oats[4,5], maize[6–8] and rice[9]. In other cases and for some additional characters considered in these investigations no consistent differences in performance were found[5,9–11]. Some of these effects have been attributed to differences in seed size[3], condition and age of the seed[5,6], mechanical damage[2] or the presence of seed-borne pathogens[6], while the level of soil fertility of the parental environment as reflected in the quality of the seed has also been implicated[3]. However, there are some instances in which it was considered that much of the variation remained unexplained[1,2]. It has previously been noted that the time of ear emergence of wheat can be modified in this way[12], but the differences recorded were ascribed to the effects of selection for earliness in a mixed population. Small changes in heading date were also found in the investigation of the influence of seed source on winter wheat[1].

In the 1960 season, single plant progenies of a New Zealand bread wheat (*Triticum aestivum* emend. Thell. spp. *vulgare* MacKey variety Hilgendorf 61) from both Canadian and New Zealand seed sources were grown together in the experimental plots of the University of Manitoba, Winnipeg, and substantial differences in the heading date were found between the two groups. Six single plant progenies from the Canadian seed source averaged 75·8 ± 2·1 days from sowing to ear emergence, while twelve similar lines of the same variety from New Zealand-grown seed from autumn sowing headed after 59·9 ± 0·4 days. In addition to being considerably later, the Canadian seed lines were much more variable in their heading date, but there was no overlap between the two groups.

In a further investigation of this effect, the Hilgendorf 61 lines were grown under three contrasting environments: both autumn- and spring-sown at Lincoln, New Zealand, and spring-sown in Manitoba. The seed produced was then grown in small plots at each of the test environments and the date of ear emergence recorded. A plot was considered to have headed when half the ears had emerged. Similar observations were taken on short rows of plants grown in boxes in an artificially illuminated growth chamber held at 70° F with an 18-h day-length. Where the plots were replicated, a randomized block layout was used.

The data presented in Table 1 are derived from four Hilgendorf 61 lines which received the most extensive testing, but they are typical in their reaction of all the lines investigated. These results indicate that while the autumn sowing of the lines did not reveal any differences in the time to ear emergence, the spring-sown plots both in Canada and New Zealand, and particularly the material sown in the growth chamber, showed substantial differences in this character.

Table 1. INFLUENCE OF SEED SOURCE ON THE NUMBER OF DAYS TO EAR EMERGENCE OF FOUR LINES OF HILGENDORF 61 WHEAT SOWN UNDER DIFFERENT ENVIRONMENTAL CONDITIONS

Seed source	Number of days to head in different test environments: Autumn sown (N.Z.) 1963–64	Spring sown (Canada) 1963	Spring sown (N.Z.) 1963–64	Growth chamber 1964
Autumn sown (N.Z.)	193·0	70·0	89·3	75·3
Spring sown (Canada)	193·0	76·5	94·6	92·2
Spring sown (N.Z.)	192·0	—	90·2	82·4
	Unreplicated, each value the average of determinations from four lines		Least significant difference 5% = 2·5 1% = 3·4	

A combined analysis of the results from replicated trials indicated that, even in cases where there was a similar average period of development, the conditions of growth affected the expression of the effect of the origin of the seeds. The interaction of the environmental conditions and the origin of the seed was very highly significant. The four individual lines of Hilgendorf 61 did not, however, differ significantly in their performance.

The use of the same lines of Hilgendorf 61 in the establishment of the seed lines from diverse sources was necessary in order to eliminate any genotypic variation which might have been present within the variety. The daily photoperiod under which the tests were conducted was longest in the growth chamber; the maximum photoperiod of the Canadian spring-sown trial was greater than that of the New Zealand spring-sown trial.

The main features of the effect of the seed source on heading date of Hilgendorf 61 are: (1) The effect of seed source had little or no influence under autumn sowing. (2) Seed derived from autumn-sown sources headed considerably earlier than other treatments under spring-sown or long-day conditions. (3) The effect was expressed as increasingly delayed ear emergence with increasing maximum day-length experienced for similar seed sources. (4) The effect was expressed as increasingly delayed ear emergence with increase in the maximum day-length to which the seed source had been exposed, under uniform test conditions.

The variety Hilgendorf 61 shows some response to vernalization treatment[13] and it could be suggested that this is satisfied by the low temperature and short-day conditions experienced during the autumn-sown cycle of seed production. If this is the case, however, the vernalization stimulus which may be acquired at the tillering stage[14] is expressed in the initiation of the reproductive stage of the progeny. Although a number of workers

have suggested that vernalization can take place in the developing grain[15–17], none have suggested that the vernalization requirement for the following generation can be satisfied at a stage earlier than fertilization. Vernalization after grain formation can be discounted, for after the time of heading of autumn-sown lines of this variety (mid-November at Lincoln) protracted cold periods are not experienced, and the day-length is in excess of 13·5 h. In addition, this explanation would not allow for the differences found between the different spring-sown seed sources. If the effect is one of photoperiodic induction alone, the nature of the mechanism and the manner by which the stimulus is transmitted through the seed stage are not known. The modifications induced are not, however, permanent changes, and the effect can be reversed by exposing the seed line to the alternative set of environmental conditions.

The profound influence of the parental environment on the performance of the progeny has important implications. It makes necessary the use of strictly comparable seed in investigations of vernalization or photoperiodic response and for the accurate comparison of varieties in field trials.

A practical application of this effect with suitable varieties would be the control of the date of heading in commercial crops. Earlier ripening of spring wheat would be an advantage in the south of New Zealand, and field trials to investigate this effect and associated differences in performance of wheat varieties are being undertaken.

GENERAL

Algorithm to assist in finding the Complete Sub-graphs of a Given Graph

Let the operation M, applied to a graph G, have the effect of removing from G all lines which are not members of at least one K_3 (a complete graph or sub-graph having three points, that is, a triangle). The new graph MG consists entirely of triangles, and it will be unchanged by a second application of the operator M. $M^2G = MG$.

This is not true of the operation D, to remove from G all lines which are not members of at least two K_3's, as Fig. 1 shows. However, D^nG converges with increasing n either to an empty graph or to a graph $D^\infty G$ of which every line is a member of at least two K_3's. This is of interest in comparison with the convergency of Boolean relation matrices[1]. Fig. 2 shows the two simplest symmetrical examples of a $D^\infty G$. Form 2(*a*) is a K_4. In the graphs investigated so far (not including crystal structure), form 2(*b*) has never occurred and every line has been a member of at least one K_4.

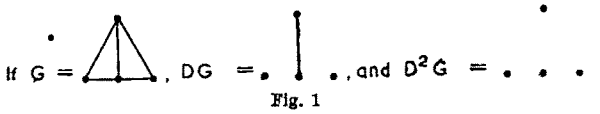

Fig. 1

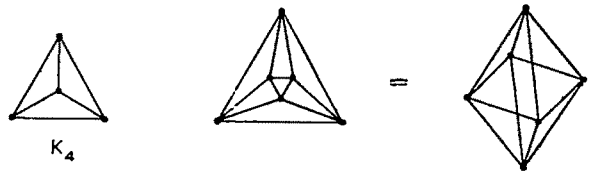

Fig. 2

Similarly, if TG is the graph left by removing all lines which are not members of at least three K_3's, all the lines in $T^\infty G$ were members of K_5's.

The time taken by a computer to find the K_4's and K_5's in a large graph is not long when the D^∞ or T^∞ algorithms are used. Applied to a graph of 1,000 points and 1,791 lines, D^4 was equal to D^8 and T^4, T^3 and T^2D were equal. After separation of the residue into its component sub-graphs, the original graph was seen to contain one K_6, twenty K_5's, and large numbers, not yet counted, of K_4's and K_3's. From an examination of the results, it seems unlikely that in this example there are any lines, like the twelve lines of Fig. 2(*b*), which belong to no K_4. Strictly, however, the algorithm should be supplemented by a test to distinguish the complete sub-graphs.

The graph-theoretical problems leading to our use of the foregoing algorithm arose out of an attempt to generate groups of words by purely mechanical operation on a large number of related documents. Words within groups were required to have strong associations with each other, and the groups were needed for research on the mechanical classification of documents. The presence or absence of each of 1,000 selected words or word-stems in each of 12,000 documents was recorded, as 1,000 binary vectors each having 12,000 bits. In comparing the vectors of every pair of words, an arbitrary test was made to decide whether the pair of words was "associated" or not. It was convenient to regard the results of the 500,000 tests as a graph on 1,000 points, each representing a word, in which a line joining two points represented an "association" between the words.

Thus, we were faced with the task of arranging the points of a large graph into groups, such that there were many lines within groups and few lines between groups. It was evident that groups of this kind would contain numerous complete sub-graphs; the algorithm provides one of several possible ways to find, first the complete sub-graphs, and then the groups.

The partitioning of graphs is becoming increasingly important in language studies, sociology, economics, network theory, logistics, automated computer design and many other situations where multiple association or correctedness is involved.

Some Observations on the Great Fire of London, 1666

1966 marks the tercentenary of the Great Fire of London. In reading descriptions of this fire, I was impressed by the facts that only four people died directly as a result of the fire and that only 436 acres were burnt in 87 h. The London fire is dwarfed when compared, for example, with the Chicago 'Mrs. O'Leary's Cow' fire of 1871 when 2,124 acres and 17,450 buildings were burnt between October 8 and 10, 250 people were killed and about

100,000 left homeless. Although fire-fighting techniques had become more advanced and buildings more widely separated than they were in the London of 1666, the Chicago fire was a much faster spreading and more destructive fire.

The reason for this great difference in fire behaviour can be attributed to the generation of a fire storm over Chicago, while there is no indication that one was formed over London in 1666. The meteorological factors giving rise to a fire storm have been discussed in detail by Besson[1] and by Ebert[2] in connexion with the Hamburg fire storm caused by air raids during the Second World War. Ebert thought that a blanket of smoke from a previous raid gave rise to very high ground temperatures and large temperature gradients with altitude, thus generating a very unstable atmosphere above the city. A low velocity ground wind was present, but apparently it did not disturb the convective column above the fire and a high velocity vortex of hurricane force was thus formed. These conditions were amazingly similar to those existing in Chicago in 1871. A large fire that had begun on October 7 was actually still smouldering when the second and larger fire began. The first fire provided a smoke cover which absorbed excessive amounts of solar energy and reduced radiation losses at night, thus raising ground temperature. Compounded with a hot, dry summer spell and a low ground wind, the conditions were ideal for the generation of a fire storm.

The presence of a steady high velocity easterly ground wind during the London fire would seem to have saved London from a larger catastrophe. Apparently, it prevented the formation of a vortex above the fire and directed the fire towards the west making it easier for the inhabitants to predict its path and thus evacuate their houses in ample time. The increase in burning rate due to a steady ground wind does not cause as much damage as that resulting from a fire storm.

The map compiled by Bell[3] was used to obtain the cumulative area burnt on different days. A plot of the square root of area versus time gives a good linear relation (Fig. 1). This is consistent with a constant linear rate of propagation. Even the last point is, as expected, slightly below the line indicating a reduction in the rate of burning. By the third day, the fire had spread outside the walls of the city where the buildings were more widely separated. At the same time, the efficient use of fire breaks and a drop in wind velocity helped to reduce the rate of progress of the fire. Since the fire perimeter was approximately semicircular, then:

$$A = \tfrac{1}{2}\pi(\bar{R}t)^2 \qquad (1)$$

where A is the total area burnt (cm²), t is the time since the beginning of the fire (sec), and $\bar{R}$ is the average linear rate of burning (cm/sec). Equation (1) gave an average linear rate of burning of 0·36 cm/sec. However, because the fire spread mostly to the west and scarcely made any progress to the east, the maximum linear velocity can be calculated by dividing the farthest distance travelled to the west (that is, between Pudding Lane and the Temple) by the total time of duration of the fire. This gives a value of 0·59 cm/sec.

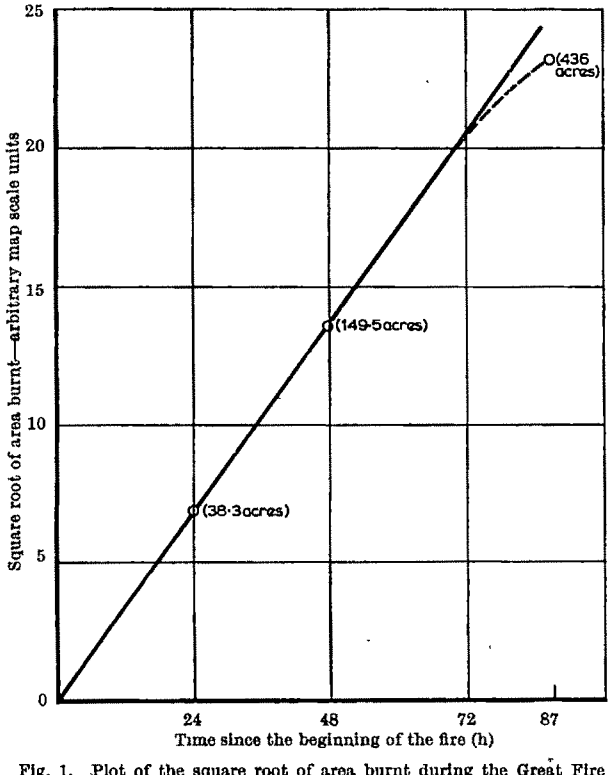

Fig. 1. Plot of the square root of area burnt during the Great Fire against time since the beginning of the fire

Since the spread of fire was more or less regular and along a relatively well-defined perimeter, it was considered of interest to compare its rate of spread with that predicted from laboratory experiments on small models.

Byram *et al.*[4] conducted several experiments in which wooden cribs of different spacings were burnt in the presence of wind and the rate of spread of fire measured. Thomas[5] showed that Byram's data could be correlated by the equation:

$$R\rho_b \cos\varphi = 0{\cdot}0085\ \mathrm{g\,cm^{-2}\,sec^{-1}} \qquad (2)$$

where ρ_b is the bulk density of the crib (g/cm³), φ is the deflexion of the flame from the vertical (degrees), and R is the linear rate of burning (cm/sec). A value of R for the Fire of London can be calculated from this equation provided appropriate values of φ and ρ_b are used.

The wind velocity during the London fire is not known, but the average wind speed at Kew Observatory varies between 10 miles per hour in January to about 7 m.p.h. in August[6]. An average wind speed of 10 m.p.h. will be assumed to have existed during the fire. Experiments on wooden crib fires in this laboratory with a wind speed of 10 m.p.h. gave an angle of deflexion, φ, of about 70°. Fire load values for several types of building have been given in the literature. Halpaap[7] gave a fire load of 125 kg/m² for a library and 200 kg/m² for a timber warehouse. Eisinger[8], in analysing the fire load of the old section of the town of Regensburg (a photograph of which showed heavy timber construction), gave a value of $11{\cdot}55 \times 10^5$ kcal/m² which is approximately equivalent to a fire load of 300 kg/m². Using this value for London (1666) and assuming an average building height of 7 m, a bulk density of 0·043 g/cm³ can be calculated. Substituting the preceding values of φ and ρ_b in equation (2) yields a value of R of 0·58 cm/sec. In view of the assumptions made, this is in excellent agreement with the maximum rate observed during the Great Fire.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Saturday, July 9

BIOLOGICAL ENGINEERING SOCIETY (at Mullard House, Torrington Place, London, W.C.1)—All-day meeting on "The British Biomedical Instrumentation Industry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

PROGRAMMER (with previous programming experience) for data processing—The Deputy Secretary, The University, Southampton (July 8).

RESEARCH ASSISTANT (with an honours degree in geography, some graphic ability and an interest in the graphic arts, and preferably experience in some aspect of map production) IN CARTOGRAPHY IN THE DEPARTMENT OF GEOGRAPHY—The Secretary of the University Court, The University, Glasgow (July 8).

LECTURER (with experience in some aspect of civil engineering hydraulics, and prepared to teach and conduct research in this field) IN FLUID MECHANICS—The Secretary, University of St. Andrews, Queen's College, Dundee (July 9).

TUTORIAL ASSISTANT (graduate with qualifications in sociology, social anthropology or a related discipline) IN THE DEPARTMENT OF SOCIOLOGY AND SOCIAL ANTHROPOLOGY, to help in the teaching of sociology—The Registrar, The University, Hull (July 9).

RESEARCH FELLOW (preferably with some experience in either kinetics of reactions in solution or transition-metal or lanthanide chemistry) IN CHEMISTRY for work on the kinetics of fast inorganic reactions in collaboration with Dr. E. F. Caldin—The Registrar, University of Kent at Canterbury, Canterbury, Kent (July 11).

DEMONSTRATORS (with good honours degree and approximately one year's research experience) IN PHYSICAL, ORGANIC OR INORGANIC CHEMISTRY—The Registrar, University College of Wales, Aberystwyth (July 12).

DEMONSTRATOR (with a good honours degree in biochemistry or agricultural biochemistry and preferably with some postgraduate experience) IN AGRICULTURAL BIOCHEMISTRY—The Registrar, The University, Newcastle upon Tyne, 2 (July 12).

LECTURER or ASSISTANT LECTURER IN SOCIOLOGY—The Registrar, The University, Hull (July 12).

LECTURER or ASSISTANT LECTURER (preferably with qualifications in mathematical physics or astrophysics) IN APPLIED MATHEMATICS—The Registrar, The University, Leeds, 2 (July 12).

SENIOR LECTURER (preferably with a special interest in thermodynamics or fluid dynamics) IN THE DEPARTMENT OF ENGINEERING SCIENCE—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devonshire (July 14).

BRITISH INDUSTRIAL PLASTICS RESEARCH SCHOLAR (with a good degree including chemistry) IN THE CHEMISTRY DEPARTMENT, for work concerned with cationic polymerization of oxygen compounds—The Registrar, The University, Keele, Staffs (July 15).

EXPERIMENTAL OFFICER (with a degree, H.N.C. or equivalent qualification) IN THE PEDOLOGY DEPARTMENT, to assist in research on soils—The Secretary, Rothamsted Experimental Station, Harpenden, Herts, quoting Ref. 1052/90 (July 15).

LECTURER IN THE DEPARTMENT OF CIVIL ENGINEERING—The Registrar, The University, Liverpool, quoting Ref. CV/118 (July 15).

SENIOR DEMONSTRATOR (graduate, preferably with a higher degree, and research experience in industry, a university or government research establishment) IN THE SCHOOL OF PHYSICS—The Registrar, The University, Newcastle upon Tyne, 2 (July 15).

SENIOR LECTURER (medically qualified) IN THE DEPARTMENT OF BACTERIOLOGY—The Registrar, The University, Liverpool, quoting Ref. CV/119 (July 15).

DIRECTOR OF THE COMPUTING CENTRE—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff, South Wales (July 16).

LECTURER and an ASSISTANT LECTURER IN THE DEPARTMENT OF BIOLOGICAL CHEMISTRY—The Secretary, The University, Aberdeen (July 16).

RESEARCH WORKER (with experience in applied respiratory physiology, and preferably a medical qualification, but this is not essential if an honours degree in physiology is held) IN THE MEDICAL RESEARCH COUNCIL'S CLINICAL RESPIRATORY PHYSIOLOGY RESEARCH UNIT—The Secretary, King's College Hospital Medical School, Denmark Hill, London, S.E.5 (July 16).

S.R.C. RESEARCH STUDENT IN THE DEPARTMENT OF PSYCHOLOGY—Head of the Department of Psychology, Queen's College, Dundee (July 16).

DEMONSTRATOR (preferably with a special interest in taxonomy or ecology) IN THE DEPARTMENT OF BOTANY—The Registrar, University College of Wales, Aberystwyth (July 18).

HOSPITAL BIOCHEMIST (Top-Grade) (appropriately qualified science graduate) IN THE DEPARTMENT OF CLINICAL BIOCHEMISTRY—The House Governor and Secretary, Royal Victoria Infirmary, Newcastle upon Tyne (July 18).

JUNIOR RESEARCH OFFICER (with, or about to obtain, an honours degree in botany, agricultural botany or a related subject) IN THE DEPARTMENT OF BOTANY to work on root competition and its relation to productivity—The Registrar, University College of Wales, Aberystwyth (July 20).

RESEARCH ASSISTANT (with a good honours degree in chemistry or biochemistry) for work on the enzymic degradation of collagen in the Rheumatism Research Centre in close collaboration with the Department of Medical Biochemistry—The Registrar, The University, Manchester, 13, quoting Ref. 162/66 (July 20).

LECTURER or ASSISTANT LECTURER (with good qualifications in astronomy with some research experience, or qualifications in mathematics or physics with experience in astronomy) IN ASTRONOMY—The Secretary, University College, Gower Street, London, W.C.1 (July 22)

RESEARCH ASSISTANT (with a first- or second-class honours degree in astronomy, mathematics or physics) IN ASTRONOMY—The Secretary of the University Court, The University, Glasgow (July 22).

LECTURER IN ELECTRICAL ENGINEERING—The Secretary, University of St. Andrews, Queen's College, Dundee (July 23).

LECTURER IN PSYCHOLOGY IN THE DEPARTMENT OF PHILOSOPHY—The Registrar, University College of Wales, Aberystwyth (July 23).

PROFESSOR OF SOIL SCIENCE; LECTURER or SENIOR LECTURER IN SOIL SCIENCE; PLANT PATHOLOGIST (Research Fellow/Senior Research Fellow); GROUNDNUT BREEDER (Research Fellow/Senior Research Fellow); and an AGRICULTURAL ENGINEER (Research Fellow/Senior Research Fellow) in the Institute for Agricultural Research and the Faculty of Agriculture, Ahmadu Bello University, Northern Nigeria—The Inter-University Council, 33 Bedford Place, London, W.C.1 (July 26).

SENIOR LECTURERS, LECTURERS or ASSISTANT LECTURERS IN (*a*) Biochemistry and (*b*) PHYSICS at the University College of Rhodesia—The Inter-University Council, 33 Bedford Place, London, W.C.1 (July 26).

CHAIR OF ORAL SURGERY at the Royal Dental Hospital of London, School of Dental Surgery—The Academic Registrar, University of London, Senate House, London, W.C.1 (July 29).

CHAIR OF MECHANICAL ENGINEERING at the University of Newcastle, New South Wales, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 30).

LECTURERS (2) IN PSYCHOLOGY at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, July 30).

RESEARCH ASSISTANT (with a university degree with distinction in petrology) IN THE DEPARTMENT OF GEOLOGY to collaborate in research on West Greenland Tertiary rocks (particularly lavas)—Dr. H. I. Drever, St. Salvator's College, University of St. Andrews, St. Andrews, Fife, Scotland (July 31).

SENIOR TEACHING FELLOWS or TEACHING FELLOWS (preferably with a Ph.D. degree or completing the requirements for the degree, and with previous teaching or research experience) IN THE DEPARTMENT OF CHEMISTRY—The Academic Registrar, Monash University, Clayton, Victoria, Australia; or the Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia, July 31).

RESEARCH ASSISTANT or TECHNICAL OFFICER (with several years experience in a physical laboratory and familiar with high vacuum techniques and electronics) IN THE DEPARTMENT OF ENGINEERING SCIENCE to be engaged in a research programme on low-frequency plasma oscillations and waves—The Administrator, Department of Engineering Science, The University, Parks Road, Oxford (August 1).

CHAIR OF PATHOLOGY at St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (August 5).

LECTURER/SENIOR LECTURER IN VETERINARY MEDICINE, at the University of Sydney, Australia—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, August 5).

HEAD (plant physiologist) OF THE CROP PHYSIOLOGY DEPARTMENT—The Secretary, Grassland Research Institute, Hurley, Maidenhead, Berkshire (August 8).

CHAIR OF EDUCATION at the University of Malawi—The Inter-University Council, 33 Bedford Place, London, W.C.1 (August 12).

LECTURER or ASSISTANT LECTURER (with interests in plant physiology and preferably research experience in plant metabolism, including radiotracer techniques) IN BOTANY—The Registrar, University College of North Wales, Bangor, North Wales (August 15).

PROFESSOR OF BIOMATHEMATICS—The Registrar, University Registry, Oxford (August 27).

ASSISTANT PHYSICIST (with a good honours degree in physics, but candidates graduating this summer will be considered) to work in the Regional Medical Physics Department on the application of physics to clinical problems in the hospital service—The Chief Physicist, Regional Medical Physics Department, 21 Claremont Crescent, Sheffield, 10.

DIRECTOR OF THE UNIVERSITY COMPUTING CENTRE—The Assistant Registrar (Establishment), The University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

JUNIOR/SENIOR LABORATORY TECHNICIAN (with chemistry A-level) IN THE DEPARTMENT OF GROWTH AND DEVELOPMENT for a research team doing specialized steroid estimating in children—The Secretary (G-6), Institute of Child Health, 30 Guildford Street, London, W.C.1.

LECTURER (preferably with an interest in statistics and/or computing) IN MATHEMATICS—The Principal, Medway College of Technology, Horsted, Maidstone Road, Chatham, Kent.

NON-MEDICAL SCIENTIFIC OFFICER (Basic Grade) FOR THE RESPIRATORY FUNCTION UNIT with related Cardio-Thoracic Unit, for work which includes various research projects in the clinical and radiological fields—The Chief Administrative Officer, United Sheffield Hospitals, Central Office, Royal Hospital, West Street, Sheffield, 1.

PROFESSOR OF ENGINEERING PRODUCTION—The Registrar, Bradford Institute of Technology, Bradford 7.

PSYCHOLOGIST (with some experience of postgraduate research, preferably in the psychology of hearing) IN THE LABORATORY OF EXPERIMENTAL PSYCHOLOGY, to work on the problem of finding a method of converting print into a sound pattern intelligible to the blind—The Assistant Registrar (Establishment), University of Sussex, Stanmer House, Stanmer, Brighton, Sussex.

RESEARCH ASSISTANT (graduate in veterinary science) to join a team of workers who are concerned with research into the control of mastitis—The Secretary, National Institute for Research in Dairying (University of Reading), Shinfield, Reading, quoting Ref. 66/23.

RESEARCH ASSISTANT (graduate or student about to graduate) IN THE DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY for research into the mechanism and control of nucleic acid synthesis—The Assistant Bursar (Personnel), University of Reading, Reading.

RESEARCH CHEMIST IN ANALYTICAL CHEMICAL TOXICOLOGY IN THE DEPARTMENT OF FORENSIC MEDICINE, to assist in a programme of research into the development of rapid methods of toxicological analysis—Dr. Harold V. Street, Department of Forensic Medicine, University of Edinburgh, Teviot Place, Edinburgh, 8.

RESEARCH DEMONSTRATORS (graduates or students graduating this summer) IN THE DEPARTMENT OF PHYSIOLOGICAL CHEMISTRY, for duties which will include assistance in practical classes and research in physiology or biochemistry, or in their application to animal nutrition—The Assistant Bursar (Personnel), University of Reading, Reading.

RESEARCH STUDENTS IN THE DEPARTMENT OF APPLIED PHYSICS to work on crystal defects in semiconducting compounds—Prof. D. A. Wright, Department of Applied Physics, University of Durham, South Road, Durham.

SENIOR TECHNICIAN and TECHNICIAN (A) to supervise the establishment of new research laboratories and to assist in the research work that is being undertaken—Prof. N. R. Butler, Department of Child Health, Children's Hospital, St. Michael's Hill, Bristol, 2.

TECHNICIAN/SENIOR TECHNICIAN (preferably with a knowledge of histological techniques) for a small experimental laboratory; and a JUNIOR TECHNICIAN (with some knowledge of animal work) for an experimental biological laboratory, for duties which will include the maintenance of a small inbred mouse colony—The House Governor, St. Mary's Hospital, Paddington, London, W.2.

TECHNOLOGY AFTER COUSINS

MR. WEDGWOOD BENN is exceedingly lucky to have succeeded Mr. Frank Cousins as Minister of Technology at this critical time for the Ministry. Ministers in charge of new departments frequently find themselves spending much time and effort in gathering together the instruments of power, often by means of tussles with their colleagues. Mr. Benn will have none of that to do. Mr. Cousins has done it for him, and there is something in the view that Mr. Cousins was too much concerned with the accumulation of power—the people, the laboratories and the money—and too little concerned with using it. Whatever the truth may be, the accession of the core of the Ministry of Aviation to his Ministry in the autumn will mean that Mr. Benn will be able, if he wishes, to direct the largest single instrument of British expenditure on research and development. By good luck there are signs that the Ministry of Technology is beginning to find its feet at last; modest achievements now exist as counterpoise for the disappointments of the past two years (see p. 115 of this issue).

What, then, should Mr. Benn do? First he must decide what the Ministry of Technology can reasonably be expected to accomplish. At the beginning of the Ministry's existence, after the General Election in 1964, ambition tended to get the better of good sense, and there was a tendency to believe that the Ministry with its own resources would be able to make up for all the deficiencies of British industry, real and imaginary. It is therefore fascinating to see how often the Ministry has been converted from taskmaster into protector. Frequently it has turned out that the best service which the Ministry can provide for an important sector of industry is not research and development but intervention with another government department, or a hint to some well-placed merchant bank. It has also become clear that the Ministry cannot hope to cater for the whole of British industry. It has to do some things well, and hope that these will serve as examples to the parts of industry not directly affected. Even with the new accession of strength from the Ministry of Aviation, it will have to remain selective. Mr. Benn must keep a tight rein on his enthusiasm.

He must also reckon that the organization of his resources will take—and will deserve—much of his attention. The laboratories within the Ministry of Technology are not by any means the coherent force they could now become. There needs to be much closer co-ordination of their work, ideally by means of the frequent interchange of people from one place to another. The aim is not to eliminate duplication, which could well be a false economy, but to arrange for the fullest exchange of creative ideas. It should also be made much easier for scientists and technologists in the new organization to move from their laboratories into the universities (and back again) and into administration. Too many of the laboratories seem like backwaters. Providing them with certain obvious common services—economic analysis or a computer centre, for example—would probably pay well, but the over-riding need is an environment in which the members of the Ministry's huge skilled labour force can sense, more clearly than at present, how valuable its work could be to industry.

Deciding how and where to exert the efforts of the Ministry is another problem. One difficulty is that there is no case law to show how best to enact the optimism which sustains the British Government in its view that intervention with public funds can indeed improve the condition of industry. So far, the Ministry of Technology has set a great deal of store by the letting of contracts to companies willing to undertake development in certain fields, and has thus done something to reproduce in Britain some of the industrial benefits of expenditure on defence research and development in the United States. There has been a brave attempt to keep the British computer industry alive and forward-looking. Good works are also now apparent in fields as different as chemical engineering and water purification. Nevertheless, the impression remains that resources are too thinly spread to be really effective. More might be accomplished by the pursuit of excellence in a narrower field—the optics industry, for example.

Already enough is known about the hazards of public sponsorship of industrial innovation to make it clear that technology as such is only half the need. In shipbuilding, for example, the Geddes Committee showed, earlier this year, that reorganization may be more important than the acquisition of new techniques. Elsewhere, British companies are often uncompetitive for lack of an incisive appraisal of the market. This is why Mr. Benn should do more than his predecessor to encourage the spread of new management techniques. Technical retraining is another neglected opportunity. Somehow the Ministry must also win a better economic insight into the condition of technology in Britain, if necessary by letting research contracts to university departments.

To this list of formidable, but mercifully tangible, tasks to be attempted, there must be added the need somehow to bridge the gulf which has grown up, in the past two years, between technology and what is sometimes called pure science. This is in part a consequence of the administrative separation of public support for science and for technology in separate departments of the British Government. No amount of committee work can guarantee good co-ordination, and Mr. Cousins's sensitivity about the autonomy of his department had not helped to foster smooth relations. But the real trouble is that the Ministry of Technology has chosen to give itself a sense of identity by accentuating the distinction between technology and science. As a consequence, the Ministry has done virtually nothing to foster the reform of engineering education in British universities

and technical colleges. Complacency about all things technological has also diverted it from a critical appraisal of the engineering professions, and from the need to pay technologists more money. On the other hand, there has grown up the view that the work of the pure sciences is somehow irrelevant to the progress of technology and the health of British industry. The best that can be said of it is that this opinion is ill-informed. Nobody knows enough to know how best to strike a balance between technology and what is now called science, although there is no question that they are in some sense mutually dependent. The best service Mr. Benn could do his Ministry, and the industry it is meant to serve, would be to convince his acolytes that science and technology are really inseparable parts of the same entity.

DATA FOR PHYSICS

THE Institution of Electrical Engineers is right to ask itself what kind of service *Physics Abstracts* should provide (see p. 112 of this issue), but there is more at stake than mere modernity. The question of whether the world's principal physics abstracting journal should continue to be published from the United Kingdom is also involved. One difficulty is that *Physics Abstracts*, like other abstracting journals, is not a paying proposition. Costs keep rising, and more or less in tune with the steadily increasing volume of publications in physics. At the same time, there is a steady pressure for an ever faster service, which means high capital expenditure on data processing equipment and the like. Yet circulation is linked not with the volume of scientific activity, but with the number of laboratories and libraries, and there are obvious limits to the extent to which it can be taxed. These are the principal reasons why subsidies are necessary. In recent years, American sources have generously helped to keep *Physics Abstracts* on its feet.

More recently, however, there has been a tendency to believe the job could be done more efficiently in the United States. Though the service offered by *Physics Abstracts* has been steadily improving, and though this is now augmented by the new journal *Current Papers in Physics*, there is no question that American experience in running abstracting journals far outstrips that in the United Kingdom. *Nuclear Science Abstracts* and *Chemical Abstracts* are both masterpieces of the application of technology to the processing of scientific information. From time to time there has actually been talk of letting *Nuclear Science Abstracts* grow so as to include the whole of physics, though the prospect of this happening is to some extent restricted by the view of the United States Government that responsibility for nuclear abstracting should belong to some international authority—the International Atomic Energy Agency, for example. In any event, there seems to be an entirely sensible recognition within the community of physicists that an efficient abstracting service must inherently be international. The American Institute of Physics has been particularly keen, in recent years, to help the Institution of Electrical Engineers along by providing timely abstracts of material appearing in its own journals. In a sense, one object of the study on which the Institution of Electrical Engineers has now embarked is to find some way of matching American efficiency with British. With luck, there is no reason why the venture should not succeed, though there are signs that American critics of present arrangements would be more easily satisfied if the Institute of Physics in Britain were more closely concerned in producing *Physics Abstracts*.

Producing abstracts quickly is, however, only half the battle. Knowing how best to use them is another problem which is harder to resolve. The most obvious difficulty is the most serious, for ordinary people find it hard to accumulate information by ploughing through the abstracting journals. This is why large laboratories provided with efficient information services have taken to distributing extracts from the abstracts to those known to have an interest in them. By all accounts, the system works well. It is certain to be imitated as widely as circumstances and machines permit, and there is no reason why even small laboratories should not be helped with selected abstracts by some central service. But how, then, to browse? Evidently there is a need for ways of letting scientists know something of the contents of a wide selection of the literature, and this is where new types of journals may have an important part to play. In all the circumstances, the Institution of Electrical Engineers should not be too dismayed if its enquiries suggest that there is only a limited future for abstracting journals as at present known. It is more important to provide the kind of service which the professionals need.

NO MORE VISITS

THE Society for Visiting Scientists has announced that it will in future not collect scientific periodicals and books and that its present collection will be disbanded This is another step in the slow process by which the Society appears to be being driven out of existence. Ever since it left its cheap-rent premises in Old Burlington Street, the Society has found it hard to make ends meet. In its annual report published in December 1965, the Society said that the "news of our financial situation is bleak. We anticipated no substantial increase in membership involving full subscription, in view of the fact that we no longer are able to provide the club amenities we used to offer". In the event the Society has found that covenants signed by a number of companies several years ago have run out simultaneously. Though some support continues, it looks as if the British Council will be the only enduring source of funds.

In spite of the vigorous programme of lectures and discussions arranged for last year, officials of the Society are inclined to be as despondent as these hard facts suggest they should be. The trouble, of course, is that the Society for Visiting Scientists must be able to help people visit, and for that it needs some premises.

NEWS AND VIEWS

More Oxford Colleges

THE Report of the Franks Commission may already have borne some fruit. The Ford Foundation of America and the Wolfson Foundation in the United Kingdom have between them agreed to contribute a total of more than £4 million to support and endow two graduate colleges at Oxford. This is the largest single sum the University has ever received, and there is some reason to think that the generosity of the two foundations has been stimulated by the argument of the Franks Commission in favour of more postgraduate teaching at Oxford. The two colleges to benefit are St. Antony's, originally founded in 1950, and a new foundation to be called Wolfson College. The latter will concentrate its interests in the sciences.

After the public announcement of the double endowment, Mr. William Deakin, the Warden of St. Antony's, said that he hopes he will be able to increase the number of postgraduate students at the College and the number of scholarships available to people from abroad. The College specializes in studies of Eastern Europe and the Far East, and plans to increase the amount of research in those subjects. The College also needs a new building, having begun its career with the ascetic view that learning comes before living, and having recently found the discomforts of a converted house in north Oxford an impediment to thought, or at least to good administration.

Wolfson College has been endowed equally by the Ford Foundation and the Wolfson Foundation to the tune of roughly £3 million. It will absorb the graduate society hitherto called Iffley College. The intention is that roughly two-thirds of its fellows should be scientists or doctors, though there will be Sir Isaiah Berlin, professor of social and political theory at Oxford, as Master (in effect though not, perhaps, in name) to redress any imbalance there may be. Mr. McGeorge Bundy, now president of the Ford Foundation but until recently Special Assistant to the President of the United States, has let it be known that he hopes that these endowments of Oxford will help to counteract the drift of people from Europe to the United States.

No Immunity against Fall-out

No general methods of immunizing man against the hazards of radioactive fall-out are likely to be forthcoming for many years—if ever. Given as many as possible of the factors relating to a particular case, some remedial measures might now be possible, but even then it would be necessary to balance the anticipated risk from radiation against the risks and social disadvantages that might result from the implementation of particular countermeasures. Such are the conclusions of the Medical Research Council's Committee on Protection against Ionizing Radiation, under the chairmanship of Sir John Cockcroft, in its report *The Assessment of Possible Radiation Risks to the Population from Environmental Contamination* (H.M.S.O., 1*s*. 9*d*.). By predicting the magnitude of the doses that will arise many years hence, and coupling this with long-term studies of the survivors of Hiroshima and Nagasaki and with other data, risk estimates have been extrapolated in terms of the possible incidence of fatal malignancies and certain genetic defects.

As a result of the atmospheric tests of nuclear weapons which had taken place up to the end of 1965, it is estimated that in the United Kingdom, by the year 2000, three additional cases of leukaemia, two of all other types of fatal cancer and two of thyroid cancer per million of the population exposed may, at the worst, have been caused. These figures refer to the increased incidence over and above the natural incidence—the figure for all types of fatal cancer (including leukaemia) in Britain is at present about 2,200 cases per million per year. It has also been estimated that, in the case of the present generation, one additional case of visible genetic abnormality could be caused in the offspring of each million persons exposed. (The natural incidence is about 15,000 per million live births.)

The report directs particular attention to countermeasures against radioactive fall-out. Iodine-131 has a considerable effect on the thyroid glands of infants. Because fresh cow's milk is the dominant route of this isotope to the body, the substitution of dried for fresh milk in the diet of infants would provide a large measure of protection: storage of dried milk would certainly offer a high degree of protection, as the activity of this isotope decreases by a factor of about 15 in every month. High concentrations of strontium-90 have been found in the bones of children between 1 and 2 years old; again, cow's milk is known to be the main source of this isotope. Remedial measures at present under examination are those designed to inhibit selectively the uptake into the body of this isotope. Thus supplementation of the diet by calcium in various chemical forms has been considered. Protection against the genetic effects are more difficult, as these are attributable primarily to external radiation and ingested caesium-137. Except in the early months of life, a large fraction of the caesium-137 that enters the body is contained in components of diet other than milk and, as the Committee emphasizes, any attempt to decontaminate these would involve major dislocation of normal food supplies.

Is a Virus a Virus?

THE World Health Organization has made public a cautionary statement on the detection of viruses associated with leukaemic tissues—human and those taken from domestic animals.

The search for virus particles by electron microscopy has to be considered as a preliminary stage only and the finding of characteristic particles as a useful guide for further biological experimentation. The absence of virus does not exclude the viral nature of the disease and the presence of particles does not necessarily mean that they are causally related to the disease. The assumption that viruses like those of avian and murine leukaemia are responsible for the human disease may not be correct. Other types of viruses or other causative agents may be involved.

If it is assumed, however, that viruses exist in leukaemic tissues from man and domestic animals similar to the viruses associated with mouse and chicken leukaemia, the following criteria for detecting particles which have a high probability of being viruses (based on observations on known leukaemia viruses) should be taken into consideration in using the thin-section and

negative staining techniques for examining tissues, cells, and pellets from associated fluids.

(*a*) *Budding particles.* The maturation (budding) process is known in detail for leukaemia viruses in mice and chickens. Confirmation of similar processes in human tissue would be good evidence of virus formation.

(*b*) *Detached particles.* These particles should possess a dense central region or nucleoid separated by a clear zone from the envelope which should have unit membrane structure. The envelope may or may not exhibit an external fringe. The nucleoid is not uniformly dense and may have a filamentous structure. The boundary of the nucleoid is sharply delimited. The presence of particles possessing a double shell, the inner of which is more electron dense and thicker than the outer, is considered to be of significance. However, the presence of particles consisting of two unit membranes, one inside the other, is not considered significant.

Particles of uniform size and consistent morphology should be present (if only isolated particles can be found identification is less certain).

The characteristics described here are important in distinguishing viruses from secretion granules, specific granules of blood cells, elementary bodies of *Mycoplasma*, etc.

In addition to these criteria, evidence for the presence of nucleic acid (presumably RNA) in the nucleoid by cytochemical methods should be sought and if found would argue strongly in favour of the viral nature of the particles.

Great caution should be exercised in the use of negative staining in the search for virus particles and whenever possible results should be confirmed by studies with thin sections. To be significant a number of particles of uniform size and consistent morphology should be present.

The avian and murine leukaemia virus particles have not so far been shown to possess the characteristic symmetrical structures that allow many other viruses to be easily recognized by this method. Nucleoids can be observed in murine and avian leukaemia virus particles if the particles are fixed before negative staining. The consistent presence of similar structures in human material would be an indication of viral nature.

The 'tails' that may be observed in leukaemia viruses after negative staining are not sufficiently characteristic to be useful as a diagnostic criterion.

This statement is being published both in this journal and in the *Bulletin of the World Health Organization.*

Engineers by Television

A PILOT experiment in the use of television for training professional engineers is to begin in Poland in September. In the first year of the project, four television production centres at Warsaw, Gdansk, Wroclaw and Katowice will broadcast five half-hour programmes each week on the Polish television network. In 1967–68 and thereafter, there will be ten programmes a week covering the material normally included in the first and second years of the Polish engineering curriculum. The pilot scheme is being sponsored by Unesco, and will be conducted in such a way that other authorities wishing to use educational television for professional training will be able to do so. Students wishing to follow the television course in engineering will be required to pass an examination so as formally to enrol and to qualify for paid study leave and the travelling expenses that will from time to time arise in visiting university centres. Formally enrolled students will also have first call on a set of text-books. It is expected that some 9,000 students will be taken on in the first academic year of the project, and that there will be room for 12,000 in later years, when instruction in the core of the engineering course is properly under way.

Enthusiasm for television teaching is clearly as high in Poland as it is wherever else television educators meet. Mr. I. Waniewitz, director of education television in Poland, says that his next objective will be a television course for training teachers. But first there is to be a thorough study and evaluation of the engineering course, not only in educational terms but also from the point of view of those concerned with cost-effectiveness. That could be a valuable piece of work.

Abstracts for Physics

WHAT information do physicists want and what is the best way of making it available? These are the questions that *Physics Abstracts* is trying to answer. The British Institution of Electrical Engineers, which publishes *Physics Abstracts*, is using £54,000 from the Department of Education and Science to carry out a 3 year study into the problems of a physics information service. According to Mr. J. R. Smith, assistant director of the Institute and head of the project, there are really four problems to be solved: (1) What is physics and what fields should it cover? The area that is now covered by the abstracts could easily be doubled. (2) What should be in the literature—should books, theses, and patents, as well as journals, be included? (3) What services do physicists actually need and want? (4) What is the best way of mechanizing *Physics Abstracts* and also turning it into an efficient information retrieval service?

The American Institute of Physics, which works jointly with the I.E.E. on *Physics Abstracts* and is co-operating on the present project, has its own documentation research project and has recently started investigating a "community network for physicists"—the information network from primary journals to the data centres required for disseminating information. The I.E.E.'s study will form a middle section of this overall review.

The British project grew out of a private conference on physics abstracting held in London in October 1964, which concluded that *Physics Abstracts* should be mechanized and that a service for information dissemination and retrieval should be established. To answer these needs, the I.E.E. is attempting to prepare a 'unit record' of each piece of data; each record will contain enough information for a variety of uses, including the present abstract journal and the current-awareness journal, *Current Papers in Physics*—a bi-monthly tabloid giving brief references for nearly all physics literature that will later be abstracted. In addition, the 'unit record' could be used for machine retrieval—straight searches for particular information, for selective dissemination of information, or for printed indexes.

Mr. Smith is hopeful that within a very few years such a mechanized system could be used for the

Physics Abstracts and the *Current Papers* at no more than the present costs; any further uses of the system would be a bonus. While there is no pressing need at the moment for mechanization, Mr. Smith said that at the present 10 per cent growth rate, now 40,000 new abstracts per year, and with a redefinition of physics, within 10 years there would be 200,000 more articles a year, an impossible number to handle by present methods. He is hopeful that when the present study ends in 1967 the Department of Education and Science will agree that a mechanized information system must be established before the present stream reaches flood level.

Parliament in Britain

In the House of Lords on June 30, Lord Byers pressed hard for an immediate further Government contribution towards the cost of the *Atlas* computer at the University of London. Lord Shackleton replied that this had been considered as part of a general review of requirements for computer time in London in the light of the Flowers Report, which the Government had adopted. Until the regional centre recommended by the Flowers Committee comes into operation, the available computer capacity would be short of the stated needs of the schools and colleges of the University of London. While the Government and the University Grants Committee would in principle wish to see the computing power available to the University of London increased, Lord Shackleton firmly maintained that the Government could not provide from available resources an additional grant for this purpose in the current year. He hoped that certain other proposals, including the early introduction of an IBM machine at University College, might ameliorate the situation.

In answering a question from Lord Chorley regarding progress with research into the desalination of sea water on June 30, Lord Shackleton said that the programme being undertaken by the Atomic Energy Authority in conjunction with industry had now been operating a little more than twelve months. Experimental multi-flash distillation facilities were in operation at Winfrith and Harwell and an additional sea-water test establishment would shortly be completed at Troon. All these facilities would be used in efforts to improve design and to reduce capital costs. Recent work on reverse osmosis had opened up the possibility of producing an improved type of membrane which was to be tested, and engineering problems associated with the design and construction of plants using this process would be studied. A new prototype electrodialysis testing unit was nearing completion.

The present programme was based on a planned expenditure of about £1·5 million over 3 years and expansion would depend on the evaluation of the technical results of current work. In this work of the Atomic Energy Authority, research and development and engineering design were very closely integrated, and thus major design studies had been made of desalination plants one order of magnitude greater than built hitherto and the possible combination of such units with nuclear power plants. There were greater hopes that the programme would lead, especially in association with nuclear power plants, to an additional source of water which would be at least as cheap as fresh water, taking into account all the equipment required for pipes and reservoirs. In view of the pressing need for fresh water, however, it was too early to cancel any existing plans.

In moving the second reading of the Overseas Aid Bill in the House of Lords on June 28, Lord Beswick said that the Bill provides authority for the Ministry of Overseas Development to use funds for certain specific immediate purposes, and the opportunity had been taken to rationalize and regularize the authority previously vested in the Ministry of Overseas Development by statutory instruments. The debate followed on one opened by Lord Todd on technical assistance to developing countries in January, and Lord Beswick affirmed the Government's belief that both Government aid and private investment had important parts to play in developing countries and that private investment was directly dependent on the creation of an infrastructure of the basic public utilities.

Total British aid had increased from £81 million in 1957–58 to £151 million in 1960–61, £191 million in 1964–65, and was expected to exceed £200 million in 1965–66; in the current year the target was £225 million. The cost-effectiveness of aid was secured by the greater co-ordination under a single responsible Ministry and by a careful scrutiny of the development programmes of individual countries. The policy of devoting a large proportion of available resources to technical aid should also assist. Dispersements on technical assistance had risen from £25 million in 1962 to £32 million in 1965. Lord Beswick also referred to the increase in contributions to multi-lateral agencies. The clause relating to the Indus Basin Development Fund Agreement was specially welcomed in the debate. The Bill was generally welcomed.

University and College News:

Battersea College of Technology

Dr. K. E. Puttick, reader in metal physics, has been appointed to the second chair of physics as from June 1.

Cambridge

The following have been appointed to the three newly established chairs of engineering: Prof. J. H. Horlock (at present professor of mechanical engineering in the University of Liverpool); Prof. L. E. Goodman (at present head of the Department of Civil Engineering and Hydraulics in the University of Minnesota); A. H. Beck (at present reader in electrical engineering in the University of Cambridge).

Manchester

Prof. D. H. Valentine, at present professor of botany in the University of Durham, has been appointed professor of botany and director of the Experimental Grounds in the University of Manchester in succession to Prof. C. W. Wardlaw. When Prof. Valentine joined the University of Durham in 1945 as reader in botany, the Department had almost no accommodation, one lecturer, a research fellow and a few students. It grew slowly but steadily; in 1950 Valentine became its first professor and his first research student began her work. This led to a tradition of experimental taxonomy which was to give the Department a firm and well-merited reputation. His own work in this field, with its emphasis on evolutionary significance rather than mere classification, is well and widely known, and many botanists will think that it is fortunate that he is taking a prominent part in the production of *Flora Europaea*. Many of his former research students occupy university posts in various parts of the

world. The vigorous and forthright manner of argument engendered by Prof. Valentine's tendency towards dogmatism has enlivened many discussions in colloquia, at society meetings, and over the departmental tea-table. This is very much relished by students at all levels, who find him a very stimulating personality. With university expansion following the usual pattern, the Department of Botany at Durham had to be content to occupy accommodation left vacant as the non-biological sciences moved into new buildings. But Prof. Valentine has ensured that the Department has maintained a proper growth-rate. As new teaching posts were created, its interests and research activities widened greatly, and he will leave behind him a flourishing and lively Department. He will be much missed.

Massachusetts Institute of Technology

DR. JULE G. CHARNEY, one of the world's leaders in the application of computers to weather analysis, has been appointed Alfred P. Sloan professor of meteorology at the Massachusetts Institute of Technology. He will be the first to occupy this new chair, established through a fund pledged by the late Alfred P. Sloan, jun., before his death early this year. Dr. Julius A. Stratton, retiring president of the Massachusetts Institute of Technology, has been elected a life member of the Corporation, the governing body. Dr. Stratton has been an *ex-officio* member of the Corporation since 1951, when he became vice-president. He became acting president in 1957 and president in 1959. Prof. H. C. Hottel has been appointed the first Carbon P. Dubbs professor of chemical engineering.

Sheffield

WHEN Prof. G. Porter vacates the Firth chair of chemistry on August 31 the Firth professorship will cease to be linked specifically to one chair of chemistry, and a Firth visiting professorship in the Department of Chemistry will be established. This will enable distinguished chemists to be invited to participate in the work of the Department. The following have been appointed to chairs: Dr. G. W. Greenwood (metallurgy); Dr. T. R. Kaiser (physics); Dr. A. S. C. Lawrence (personal chair in the Department of Chemistry).

Sussex

DR. A. M. UTTLEY, at present superintendent of the Autonomics Division at the National Physical Laboratory, has been appointed research professor of experimental psychology in the University of Sussex, and he is to lead an important scientific project concerned with the application of pattern recognition theory to our understanding of the organization of nerve cells in the brain by using a computer to set up simulated models. The work is to be supported by a Science Research Council grant of £72,000 over a period of 5 years, and Dr. Uttley has also been awarded a grant by St. Dunstan's of £7,000 per annum for 5 years, to support research on reading aids for the blind. In addition, the Carnegie Institution of Washington has made a grant of £9,000 in support of Dr. Uttley's research work. The Science Research Council has also made an award of £19,000 to Prof. N. S. Sutherland, head of the Laboratory of Experimental Psychology at Sussex. He will be comparing models of perception and learning with data derived from psychological studies of human and animal subjects.

Announcements

DR. HENRY B. BIGELOW, founding director of the Woods Hole Oceanographic Institution, has been awarded the Compass Distinguished Achievement Award at the annual meeting of the Marine Technology Society in Washington, D.C. Dr. Bigelow has served as president of the Corporation of the Institution, as chairman of the board of trustees and as curator of the Museum of Comparative Zoology at Harvard University; he is now an honorary trustee of the Oceanographic Institution and professor emeritus of zoology at Harvard. The Award is given by the Marine Society "for significant contributions to the advancement of the science and engineering of oceanography and marine technology".

R. D. GILLARD has been awarded the Meldola Medal for 1965 in recognition of his work in the field of inorganic chemistry, with special reference to the chemistry of transition-metal complexes and their optical activity

DR. TOBIAS LASSER, director of the Botanical Institute, Caracas, Venezuela, was confirmed as president of the Association for Tropical Biology for 1966–67 at the meeting on the Biota of the Amazon Basin, held in Brazil during June 6–11. Dr. A. C. Smith of the University of Hawaii was elected president-elect.

SHELL research fellowships have been awarded to Dr. R. B. Homer, University of East Anglia, to support his research on the interaction of small molecules with biopolymers, and to Dr. Margaret Wright, University of St. Andrews, for kinetic and equilibrium studies of the hydrolysis of biologically important compounds; and some aspects of enzyme kinetics relevant to haemolysis. These awards are worth £1,300 per annum and are tenable for 2 years from October 1966. They are the first to be made from Shell International Petroleum Company's new series of post-doctoral research fellowships.

THE annual report of the Smith Kline and French Foundation for 1965 says that grants made by the Foundation in the first 4 years of its existence amount to £103,347. The Foundation specializes in small grants (less than £2,500 each) for research in medicine and related fields. Further information can be obtained from the secretary, Mr. A. T. Cousins, Mundells, Welwyn Garden City, Hertfordshire.

AN exhibition to commemorate the centenary of the second term of office of Sir Joseph Whitworth, arranged by the Institution of Mechanical Engineers in conjunction with the Whitworth Society, will be held at the Institution of Mechanical Engineers during July 19–August 26. Further information can be obtained from the Secretary, Organizing Committee, the Institution of Mechanical Engineers, 1 Birdcage Walk, Westminster, London, S.W.1.

A SUMMER institute on "Non-Linear Effects in Plasmas" will be held in the University of Paris during September 5–23. Further information can be obtained from Dr. Kalman, JILA, University of Colorado, Boulder, Colorado.

A JOINT meeting of Commissions II and IV of the International Society of Soil Science on "Soil Chemistry and Fertility" will be held in King's College, University of Aberdeen, during September 5–10. Further information can be obtained from Dr. J. Tinsley, Department of Soil Science, University of Aberdeen.

THE annual symposium on "Molecular Structure and Spectroscopy" will be held in the Department of Physics, Ohio State University, during September 6–10. Further information can be obtained from Prof. K. Narahari Rao, Department of Physics, Ohio State University, 174 West 18th Avenue, Columbus, Ohio.

AN advanced study institute on "Symmetry Principles in Elementary Particle Physics", under the directorship of Prof. B. Kursunoglu, will be held at the Cekmece Nuclear Research Center in Istanbul during August 8–27. Sponsored by the North Atlantic Treaty Organization, the summer institute will be directed primarily to advanced graduate and postgraduate students. Some funds will be available for those unable to obtain complete financial support elsewhere. Further information can be obtained from Prof. A. Perlmutter, Center for Theoretical Studies, University of Miami, Coral Gables, Florida.

THE SHORT HISTORY OF THE MINISTRY OF TECHNOLOGY

THE British Ministry of Technology was created in October 1964, after the General Election in that year. The plan for such a Ministry was itself an important part of the discussions within the Labour Party in the months preceding the election. The chief argument in its favour was that the government of a modern industrial nation requires a concentration of power in an organization capable of initiating change. To begin with, critics of the then arrangements for sponsoring and fostering industrial development and research were able to point to the diversity of the interests concerned—the Department of Education and Science, the Ministry of Aviation, the Board of Trade, the Ministry of Power, not to mention a number of independent public bodies such as the United Kingdom Atomic Energy Authority. The first objective, then, was to unite as many as possible of these entities in one organization.

In the event, the Ministry of Technology created in October 1964 was less grand. In the arrangements for organizing civilian science and technology, the Department of Education and Science has retained responsibility for the research councils whose chief function is to support scientific research in universities and elsewhere, but which also carry out some work of their own. (Thus the Science Research Council is directly responsible for running the Radio and Space Research Station at Slough.) The Ministry of Power remains formally responsible for fostering scientific research in power generation, while, for most of the past twenty months, the Ministry of Aviation has retained responsibility for a number of research establishments, some of which are directly concerned with defence and others with more civilian developments, and has thus been an ironic reminder that some of the earliest plans for the Ministry of Technology assumed that it would be constructed around the Ministry of Aviation.

To begin with, the Ministry of Technology was made responsible for ten research stations transferred from the old Department of Scientific and Industrial Research (Table 1), together with the United Kingdom Atomic Energy Authority. At the same time the Ministry of Technology was made responsible for the co-operative research associations, which were again transferred from the Department of Scientific and Industrial Research and which are financed partly by government grant and partly by contributions from the industries concerned. The Ministry of Technology was also, from its creation, given responsibility for the National Research and Development Corporation, whose job it is to invest public money in the development of new processes and devices (the most profitable of which has been the Bailey bridge and the best known the Hovercraft). The Ministry of Technology became formally responsible for these various institutions within a few months of the creation of the Ministry; the transfer of power was complete by the beginning of April 1965.

The Atomic Energy Authority consumes roughly ten times as much money as the laboratories and engages not merely in research and development but also in the production of nuclear materials and the processing of spent uranium fuel. Since the inception of the Ministry of Technology it has been assumed that the Atomic Energy Authority will somehow diversify its activities, taking on pieces of research and development on behalf of industry. As yet, there is little to show how successful this policy has been.

With its creation, the Ministry also assumed responsibility for the industrial research associations, now forty-eight in number and requiring annual expenditure

Table 1

	1966–67 Cost (£)	No. of people
Building Research Station	936,000	693
Fire Research Station	187,000	149
Forest Products Research Laboratory	239,000	177
Hydraulics Research Station	257,000	285
Laboratory of Government Chemist	570,000	395
National Engineering Laboratory	940,000	795
National Physical Laboratory	2,216,000	1,661
Torry Research Station	229,000	198
Warren Spring Laboratory	505,000	398
Water Pollution Research Laboratory	228,000	171
	6,307,000	4,872

estimated to amount to £3,570,000 in 1966. In addition, the Ministry is reckoning to spend £750,000 on research and development contracts, a roughly similar amount on a scheme to purchase from industry advanced machine tools and other devices where it is thought that development is held up for lack of customers, £700,000 on advice for industry, £290,000 in launching the National Computing Centre, and £400,000 on support for the British Standards Institution.

As yet, it is not clear how much of the work of the Ministry of Aviation will be transferred to the Ministry of Technology in the autumn of this year. One of the first tasks to be tackled by the new Permanent Secretary to the Ministry of Technology, Mr. Richard Clarke, will be to work out a rational division of the Ministry of Aviation. Some of the defence research establishments will no doubt be transferred to the Ministry of Defence, but it seems clear that the Ministry of Technology will also grow in the process. Certainly its capacity for research will be strengthened in solid-state physics, electronics, and aerodynamics.

In its responsibility to Parliament for the National Research and Development Corporation, the Ministry of Technology has been able to sponsor an increased budget. In the year ahead it plans to invest a further £5 million of public money in the work of the National Research and Development Corporation. At the same time it has been agreed that the Corporation should write off some £2·5 million of interest accumulated since 1947 on capital borrowings from the Treasury and unlikely to be paid in the near future. To the extent that this step represents an admission that an organization instructed to take chances on research and development projects cannot always make a profit, it is likely that the Corporation will now feel more free than it has done to engage in risky enterprises.

Apart from its direct responsibility for institutions like these, the Ministry of Technology has an avuncular relationship to British industry as a whole. Much of the energy of its officials has gone into detailed enquiries into the state—technical and economic—of particular sectors of industry. There have, for example, been enquiries into machine tools and optics. The Ministry is not merely concerned to find out; it also hopes that the process of enquiry will stimulate industries to seek remedies for problems which become apparent.

In recent months the Ministry has been particularly active internationally. For one thing, it is trying to introduce British manufacturers to standards (of measurement and of specification) in use elsewhere in the world, in the hope of making exports easier to come by. It is also spending an increasing amount of its energy in dealing with the difficulties which beset British manufacturers wishing to sell things abroad, sometimes using its influence to persuade another department of the British Government to remove some fortuitous obstacle to trade.

CONTINENTAL DRIFT, MESOZOIC CONTINENTS AND THE MIGRATIONS OF THE ANGIOSPERMS

By DR. R. MELVILLE
Royal Botanic Gardens, Kew

THE origin of the flowering plants, how they came to appear relatively suddenly in the northern hemisphere in the Cretaceous and how they attained their present distribution are different aspects of one of the outstanding problems of biology. In recent decades it has become increasingly evident that the angiosperms must have had a long evolutionary history before the Cretaceous. Hawkes and Smith[1] recently supplied evidence favouring the existence of the genera *Gossypium*, *Bromus* and *Solanum* early in the Cretaceous and suggested an origin much earlier and probably on the former continent of Gondwanaland. Stebbins[2], Thomas[3] and Camp[4] have reached similar conclusions from studies of living angiosperms, and Plumstead[5] has reviewed the fossil Glossopteridae, which dominated the flora of Gondwanaland, and discussed the evidence linking them with the angiosperms. In evidence drawn mainly from floral vascular systems, I have proposed[6–8] a new theory of floral evolution, which indicated the Glossopteridae as the probable ancestral group of the angiosperms. The problem is too complex to be solved by any single line of evidence, but requires the correlation of data from many fields including taxonomy, phylogeny, palaeobotany, palaeogeography, geomorphology and palaeomagnetism.

The critical period for this study extends through the Jurassic and Cretaceous when Mesozoic land masses were breaking up before their rearrangement into the present continental system. Before this upheaval, during the Palaeozoic and the early part of the Mesozoic, four great floral regions can be distinguished. Three of these were in the northern hemisphere and the fourth occupied the former Gondwana continent, which endured in the south from about the Silurian until it began to break up in the Jurassic. Palaeobotanical evidence does not indicate any contact between Gondwanaland and the northern continents during the whole of this long period[5,9]. Recent palaeomagnetic research has provided independent evidence for the continued existence of the Gondwana continent at this time[10].

By the Carboniferous, the Glossopteridae had developed as the characteristic flora of Gondwanaland. In the northern hemisphere, the coal flora occupied western Europe and eastern North America, which together formed a continent centred over the North Atlantic, which may be called Atlantica. A second distinctive flora, the *Gigantopteris* or Cathaysian flora, occupied a large part of China and South-east Asia and also the western part of North America[9]. These regions formed a continent centred over the North Pacific which may be called 'Pacifica'. In the region between, the Angara flora occupied an area covering Siberia southwards to about the present 40° parallel of latitude. At a later epoch the orogenesis which split up and dispersed Gondwanaland also cleft in two both Atlantica and Pacifica. Western Atlantica drifted into contact with Eastern Pacifica to form the present North American continent. The other two fragments, Eastern Atlantica and Western Pacifica, contributed to the modern Eurasiatic landmass. We must now seek evidence for the boundaries of these ancient continents and their positions at the beginning of the orogenesis.

Geological discontinuities along the sites of ancient geosynclines mark the boundaries of the former continental fragments, which came together to make the present continents. The distribution of earlier floras can be traced from the fossil record and can be correlated with the geological evidence to make a reconstruction of the former continents before their rearrangement. Following this line of research, we find that fossil Glossopteridae occur in South America only south of the Amazon, so that only the southern portion can have formed part of Gondwanaland. The Amazon itself is no ordinary river. Although it runs for more than 2,000 miles through country not more than 36 ft. above sea-level its channel is broad and deep. At 500 miles above Para the river is still 348 ft. deep[11]. These unusual features can be accounted for if the river follows a rift where continental blocks came together.

Crossing the Atlantic to the African shore, a deep trench is found in the seabed in latitude 8–9° N. off Sierra Leone[12]. This probably marks the junction between the north-west portion of Africa, which yields no *Glossopteris* fossils, and the remainder of the continent which formed part of Gondwanaland. From 10° N. on the coast, the boundary of the old Gondwana block skirts around the uplands of Futa Jalon and then follows roughly the line of the Niger to Timbuktu. Thence it runs northwards to skirt around the Ahaggar massif and follows the line of the high ground around to the mouth of the Nile. Arabia belongs with Africa to Gondwanaland, and the boundary then follows the coast of the Mediterranean to the head of the Gulf of Iskenderun. From this point it turns eastwards, following the southern boundary of the Anatolian Mountains and finally south-eastwards along the edge of the Zagros Mountains to the Persian Gulf.

Passing eastwards, India forms the next Gondwanic block. The boundary of the *Glossopteris* flora has been discussed by Sahni[13]. From Karachi it follows the valley of the Indus to the Himalaya, then along the line of the Himalaya to about long. 100° E., lat. 30° N. From this point it turns southwards along the line of the ranges between the Salween and Mekong rivers to Malaya. Sahni took the boundary along the spine of Malaya, but was uncertain whether or not to include Borneo as part of Gondwanaland. Some fossil Glossopteridae have been found in Borneo[9] which forms part of the Oriental faunal region[14]. The Wallace line, which passes along the Makasar Strait between Borneo and Celebes and through the deep strait between Bali and Lombok, marks the boundary of two distinctive faunal provinces. From what follows in this article, it is probable that it also is part of a Gondwanic boundary, the islands to the west, Sumatra, Java, Bali and Borneo, with the whole of Malaya forming part of the Indian block of the Gondwana continent.

The whole of the Australian continent belongs without question to Gondwanaland, but doubt remains about

New Guinea. The similarities between the floras are too slight for New Guinea to have been associated with Australia for a long period, as pointed out by Good[15]. It has been excluded in the present reconstruction except for the Merauke Ridge. The presence of the Upper Gondwana flora in New Zealand indicates its origin and with it must go the extensive ramified block on which it stands, the greater part of which is now submerged. The associated islands include New Caledonia, Fiji and Samoa, and to the south, Macquarie and Campbell. Finally, the whole of Antarctica belongs to Gondwanaland; fossil Glossopteridae are known from both east and west provinces[5].

The present positions of the fragments of Gondwanaland are shown in Fig. 1. Because the boundary line has been determined primarily from the distribution of the Glossopteridae, it will be convenient to call it the 'Glossopterid Line'. The general trend of this line is confirmed by the distribution of other fossil and modern gymnosperms. Florin[16] has established that different groups of gymnosperms occupied the northern and the southern (Gondwana) continents in the Palaeozoic and Mesozoic up to the end of the Jurassic. Taking Podocarpus as an example of the southern group, all its fossils are south of the line, and the living species only transgress the line in South-East Asia and in the North Amazonian province of South America and Central America, where they have migrated since the beginning of the Cretaceous. Conversely, fossil pines (*Pinus*) are only known north of the line and the modern species only cross the line into Syria, and small areas in Burma and Sumatra.

Any reconstruction of the Gondwana continent should take into account the physiography of the ocean basins and palaeomagnetic and biological data. In the solution offered by King and Downard[17], India is not in a position consistent with drift along the line of the two great transcurrent faults of the Maldive–Laccadive and Ninety-East degree. They also place the New Zealand block in contact with Eastern Australia, a position inconsistent with the absence of the large Australian genera *Eucalyptus* and *Acacia* from New Zealand. Creer's partial reconstruction[10] based on palaeomagnetic data also requires adjustment in the light of other evidence, while that of Ahmad[18] conflicts with the position of ocean rises and the Carboniferous glaciation. The mid-oceanic rises may be used as the starting-points for the reassembly of the dispersed fragments. The Gondwanic portions of Africa and South America can be fitted along the South Atlantic Rise in the positions worked out by Bullard *et al.*[19a]. The position of the combined block must have been somewhat to the south before the break-up of Gondwanaland and in contact with Antarctica. Menard's map of the Pacific basin[20] shows some remarkable coincidences between the shape of the submerged continental platform of east Antarctica and that of the Pacific–Antarctic Rise, which fixes a position for Antarctica. This would bring the coast east of the Weddell Sea in contact with Africa. The Malaysian part of the Indian block must have been in contact with peninsular India. The two parts fit together along the Ninety-East fault if the Malayan peninsula is flexed at its narrowest point to straighten it. By moving the Indian block so assembled southwards along the Ninety Degree and Maldive–Laccadive faults, it fits into the arc of the South Indian Rise in proximity to the new position of Antarctica. No palaeomagnetic data are available to check the position of India, but Irving and Green[21] have given a pole position for the older volcanics of Victoria, estimated to be of older Pliocene age, which would bring that part of Australia over the Indian–Antarctic Rise and considerably to the west of its present position. For this to be possible in relation to the remaining parts of Gondwanaland, Australia would need to be rotated through a right angle into the position shown in Fig. 2. This would imply very little change in latitude for Western Australia since the Jurassic, but considerable changes in latitude and climate for Eastern Australia. Such a sequence of events is consistent with the high proportion of endemics in the Western Australian flora and the survival of many relatively primitive forms in that area. Finally, the New Zealand block must have been to the south-east along the Pacific Antarctic Rise opposite Eastern Antarctica. Palaeomagnetic evidence is unfortunately wanting for this area.

The extent and direction of the Carboniferous glaciation as recorded by Holmes[22] may be used as an independent check on the validity of the reconstruction. With the proposed assembly the glaciated area would be nearly circular and the directions of the ice flow (Fig. 2) are in good agreement. The positions for Creer's South American poles 14 and 15 (ref. 10) lie close to the apparent geographical pole and are consistent with the reconstruction.

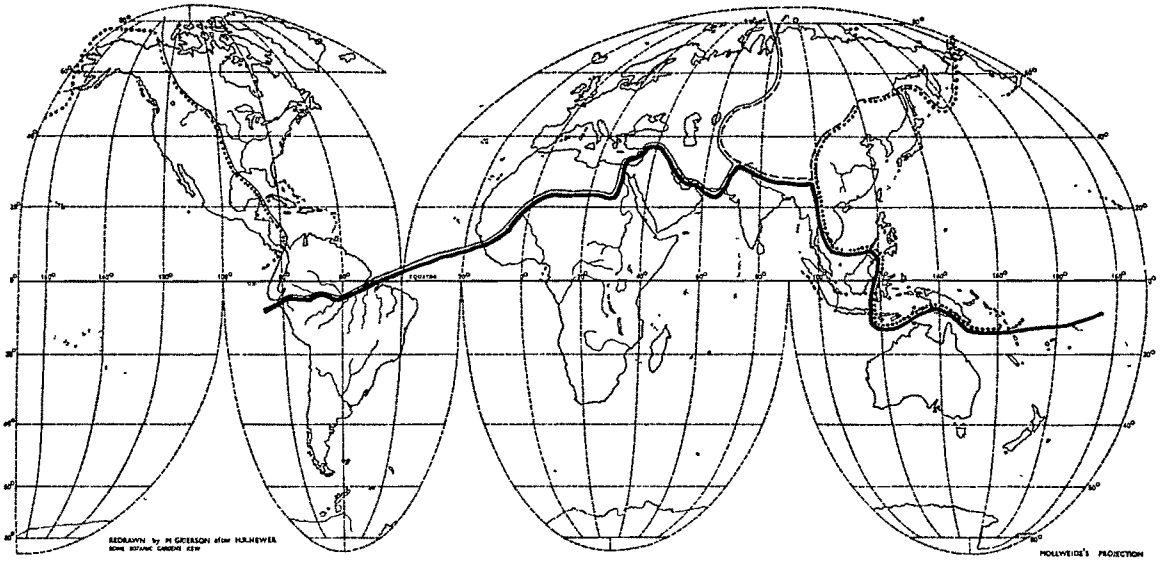

Fig. 1. Palaeozoic floral regions. Heavy line, the glossopterid line marking the northern boundary of the fragments of Gondwanaland; thin line, boundary of the Carboniferous coal flora; dotted line, boundary of the *Gigantopteris* flora; broken line, boundary of the Angara flora

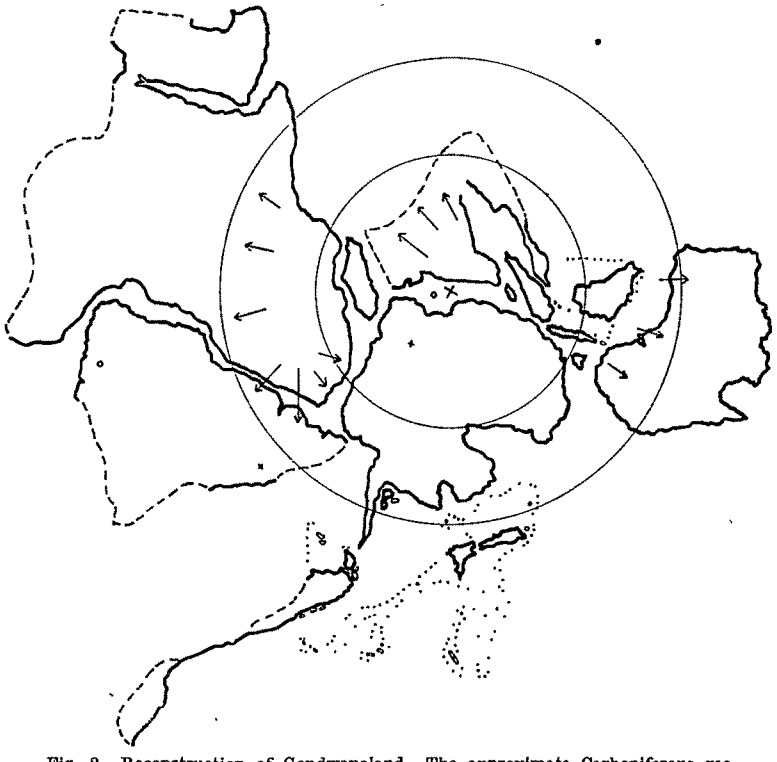

Fig. 2. Reconstruction of Gondwanaland. The approximate Carboniferous geographical south pole is marked, with the Antarctic circle and 50° circle of latitude which nearly coincides with the limits of the Carboniferous glaciation in South America, Africa, and Australia. Creer's South American palaeomagnetic poles Nos. 14 and 15 are shown with their conjugate points. Dotted lines, continental shelves; broken lines, severed continental boundaries; arrows, direction of Carboniferous iceflow

Turning now to the northern hemisphere, the fit of the two sides of the North Atlantic as calculated by Bullard[19a] can be accepted, except that further consideration must be given to the non-Gondwanic portions of Africa and South America. There is reason to think that north-west Africa formed part of Atlantica, as Wilson[19b] has directed attention to the fact that Hercynian fold belts of this region complete the southern part of the Newfoundland—Virginia belt of the same age. No such guide is available for the north Amazonian block of South America. Palaeomagnetic data are lacking for both areas. No fit can be made between the Caribbean shores of the Americas as they exist at present. Before the reconstruction of Atlantica can be attempted the part of North America which before the Jurassic formed part of Pacifica must be removed. The boundary as indicated by fossils of the *Gigantopteris* flora[9] runs southwards from the mouth of the Mackenzie River skirting east of the Rockies to a point on the Gulf of Mexico west of the Mississippi delta (Fig. 1). The presence of marine deposits of Permian to Jurassic age in the Mackenzie basin is consistent with this boundary[19b], which is confirmed by Schuchert's palaeogeographic maps for these periods[23]. The low-lying Florida peninsula formed of Cretaceous and later sediments did not exist at the period with which we are concerned. Jurassic seas pierced the central American isthmus in two places and an arm of the Jurassic sea must have penetrated as far as the Cape Verde Islands to account for the only marine Jurassic deposit along the whole of the Atlantic[19b]. Probably block faulting across the south-western part of Atlantica was responsible for these effects, separating the Greater Antilles, which can be fitted neatly along the northern coast of South America. If, now, the North Amazonian block is moved into position against North America, Atlantica will be complete.

By the end of the Jurassic the South America–African block must have drifted into contact with south-eastern Atlantica in the position shown in Bullard's reconstruction. A large bay then separated south-west Atlantica from South America, the eastern end of which is shown in Bullard's reconstruction as an anomalous triangular gap.

Little attention has been given to the possibility of a mid-Pacific continent in the Mesozoic, but the evidence for the existence of Pacifica is of the same kind as that for Atlantica. In both cases the present oceans are flanked by continents bearing the severed halves of a Palaeozoic flora—respectively the *Gigantopteris* and the coal floras. In both there is a mid-ocean rise which marks the line of the upwelling convection current that caused the severance of the former continents, that for the Pacific being called the Darwin Rise by Menard[20] to distinguish it from the East Pacific Rise. Over the significant areas of both oceans no fossils or datable material of pre-Cretaceous age have been found[19b,20]. Much evidence from geological coincidences[19d] and palaeomagnetic measurements[19c] supports continental drift in the Atlantic. The evidence for the Pacific is much less complete, primarily because far less attention has been given to it.

Two periods of regional metamorphosis are reported for Japan[19e], 200 and 100 million years ago, which would correspond with block faulting in the Permian and later volcanism accompanying drift in the Cretaceous. Western North America was geosynclinal in the late Mesozoic[19f] when drift was closing the gap between the western and eastern parts of the continent. Palaeomagnetic results for western North America are discordant with those from the east and indicate a former separation. No palaeomagnetic data for the Mesozoic of China have come to my notice, but the poles calculated by Deutsch and Watkins[24] for the Triassic of the Tunguska River region of Siberia indicate a position of the Angara block 25° south and 87° to the east of its present position. For this to be true, the Angara block must have been in contact with Cathaysia at that time, when the present coast of China was in the middle of the Pacific. The augmented Pacific continent must have been in existence at least from the Triassic until it broke up early in the Cretaceous, but the Cathaysian core extended back to the Carboniferous.

An attempt can now be made to reconstruct Pacifica. The fragments can be assembled along the line of the Darwin Rise in its present position. No difficulty arises in placing the western American portion, but the island arcs off the eastern coast of Asia must be closed up to form a compact mass against the continental shelves. In Fig. 3, the deeps of the enclosed seas of Okhotsk, Japan, and East and South China are eliminated and the peninsulas of Kamchatka and Korea have been folded against the continental margin; Borneo and the parts of Malaysia which do not form part of Cathaysia have been removed. New Guinea, which floristically and geologically is distinct from Australia[15], has been placed in a position to fit the curvature of the Darwin Rise, and so complete the continent.

From the Jurassic to the Cretaceous another land mass existed in the South Pacific. This consisted of the New Zealand block together with Antarctica assembled along the line of the South-east Pacific Rise in the position already indicated for the reconstruction of Gondwanaland. In addition, it is probable that the Andean provinces of South America, embracing Peru, Bolivia, Chile and Western Argentina, south of the Gulf of San Jorge with

Fuegia and the Falklands, were situated along the eastern edge of the rise. The eastern boundaries of these provinces are marked by a line of marine Jurassic sediments[25]. Allowance has been made in the reconstruction for the displaced section of the rise south of the Easter Island fault. Palaeomagnetic data are wanting for this South Pacific continent, but it is supported by the distribution of numerous plant genera and species and by the absence of Carboniferous glaciation in Patagonia.

For the biologist, the timing of the various episodes in the break-up of the Mesozoic continents is of the utmost importance. The moment of severance limits the migration of land organisms by normal methods and must be a major factor in determining modern distributions. Evidence for stages in the break-up of Atlantica is more complete than for any other continent. The initial faulting which demarcated Greenland occurred in the Carboniferous[19g]. Marine invasions in this area began in the upper Permian and continued with recessions through the Triassic. Progress of the rift was slow until the beginning of the Cretaceous and then proceeded rapidly southwards along the North American coast.

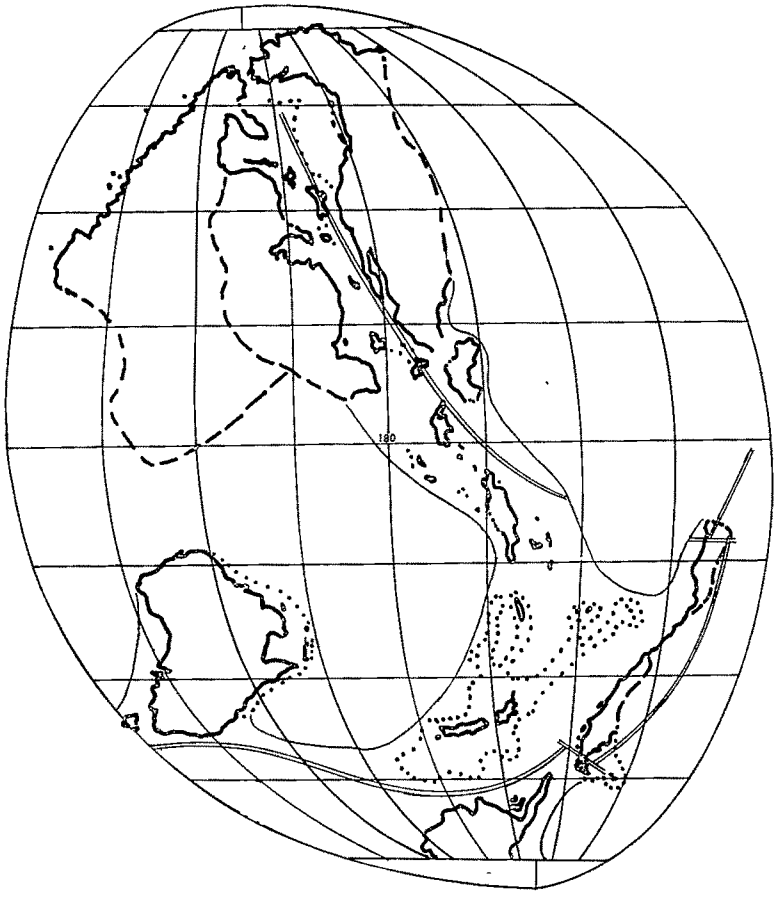

Fig. 3. The central Pacific continent, Pacifica, at the close of the Jurassic. A thin line marks the approximate limits of the isthmus joining Pacifica to southern Gondwanic lands. Double lines, the position of the Darwin and East Pacific Rises; dotted lines, continental shelves; broken lines, severed continental boundaries

Africa and South America began to drift away from the remainder of Gondwanaland in the upper Permian according to palaeomagnetic evidence[10]. Assuming this date to be accurate, the general trends of evolution in the angiosperms must have been determined by this time although their fertilization mechanism may still have been gymnospermous. Progenitors of such families as Proteaceae, Leguminosae and Restionaceae must have been dispersed through both African and Australian provinces of Gondwanaland to account for their modern distribution. The African province drifted towards Atlantica and probably made contact with south-east Atlantica during the Jurassic. Faulting along the line of separation between Africa and South America must have then been far advanced, as the separation followed rapidly on that of Europe and North America and was completed early in the Cretaceous. It is probable, therefore, that Africa was in contact with Atlantica for a large part of the Jurassic, time enough for a considerable migration of angiosperms before the Atlantic Ocean developed.

The faulting which heralded the break-up of Pacifica—the rift valley phase—was probably well advanced by the late Triassic. It was accompanied by metamorphosism in the Japanese region and followed by a second phase of metamorphosism in the late Cretaceous[19e], which must have marked the final stages of the drift. The uprising convection current under the continent raised the land surface 2–3 km along the line of the Darwin Rise. At the southern end this caused the formation of a land-bridge between Pacifica and the New Zealand block, linking the regions now forming New Guinea, New Caledonia and the western fragments of South America which then formed part of the southern Pacific land mass. This land bridge must have formed early enough to allow a few representatives of the *Glossopteris* flora to reach Kansu in the Triassic[9]. It was the major link between Gondwanaland and the northern continent and accounts for the high concentration of relatively primitive angiosperms which still survive in south-east Asia and New Guinea and New Caledonia. Contact between north and south continued longer before the drift started than that between Africa and Atlantica, but the onset of drift was probably early in the Cretaceous to account for sedimentation in the Pacific basin and the ages of atolls and guyots reported by Menard[20].

The next phase in the disruption of Gondwanaland was the development of the mid-Indian rise which continued south-eastwards through the junction between Australia and Antarctica. Evidence to date the northward drift of India is scanty, but it may have started in the mid-Cretaceous, and contact was made with the Angara–Cathaysia block by the Palaeocene, though folding of the Himalaya continued into the Oligocene[19b]. The drift of India was relatively rapid and, in its passage north, the resulting climatic changes caused the almost complete annihilation of its rich gymnosperm flora[18]. Perhaps for the same reason, India appears to have made a smaller contribution to modern floras than its size would warrant.

Concurrently with the drift of India, Australia was pushed eastwards along the line of the Diamantina fracture zone[19f]. The centre of activity moved eastwards along the Indian–Antarctic rise, driving eastern Australia northwards late in the Cretaceous. The combined movements caused the rotation of Australia, bringing it into contact with New Guinea which, by this time, had drifted to the south-east of its present position. New Guinea was forced northwards and the adjacent island arcs were curved into their present positions. The rift continued eastwards along the line of the Pacific–Antarctic Rise and then north-eastward along the East Pacific Rise, separating the New Zealand block from Western Antarctica and from the Chilean and Peruvian fragments of South

America at the end of the Cretaceous or Palaeocene. The final stages of the movement caused the raising of the Andes in the Miocene.

Before the break-up of Gondwanaland, continuous land connexion existed between India, Antarctica and eastern Australia (Fig. 3). With the development of the East Pacific Rise, the gap between Australia and New Zealand across the Ross Sea area must have been bridged. It is evident that during the Cretaceous the circum-Antarctic land bridge postulated by plant geographers from Hooker[26] to van Steenis[27] actually existed. The reason for such sub-Antarctic distributions as that of *Juncus scheuchzerioides* in Kerguelen, Tasmania, New Zealand, Fuegia and the Falklands is now clear. The separation of the New Zealand block from the Chilean fragments of South America was late enough to account for the identity of the small number of *Hebe* species in the latter area with their New Zealand congeners. The genus *Nothofagus*, at present with a disjunct distribution in Tasmania, Eastern Australia, New Guinea, New Caledonia, New Zealand, Chile and Western Antarctica (fossil), in the Cretaceous occupied a single land area. *Coriaria*, now inhabiting New Zealand, South America and China with one species in Europe, was able to migrate from its Gondwanic home to China in the early Cretaceous, and, after drift, across to Europe. Pleistocene glaciation probably accounts for its absence now in the rest of temperate Asia. The links between the floras of Japan and South America discussed by Maekawa[28] can be explained on the basis of pre-existing land connexions. So also can other distributions mentioned by Camp[4], and it may be found profitable to compare the maps published by Vester[29] with the disposition of land in the Jurassic and Cretaceous as revealed by the present synthesis.

Although parts of these reconstructions may appear to be somewhat speculative, every position mapped rests on evidence from two or more disciplines. It is hoped that the attention drawn to gaps in our knowledge will lead to further research on related problems. I am grateful to Dr. E. P. Plumstead for discussing the distribution of the *Glossopteris* flora and to colleagues at Kew and the British Museum for their interest and encouragement.

BOOK REVIEWS

UNBRIDLED RACISM

Racial Contours

The Factor of Race in Human Survival. By H. B. Isherwood. Pp. 423. (Douglas, Isle of Man: Times Press, Ltd., 1965.) 18*s*.

READING this book is a disheartening experience. It is scarcely credible that such congeries of misrepresentation, warped judgment, and just plain gibberish can be published in the Age of Science, and in Great Britain rather than in some underdeveloped country. Here are some samples: ". . . we have no alternative but to assume that from the statistical analysis there are fewer genes (or less complex gene combinations) in the lower primates than in, say, the Australoids, even though they may have the same number of chromosomes, that also there are fewer genes in the lowly Australoid than in, say, the Negroid, and that there are fewer genes in the Negroid than in the Mongoloid". The blue-blooded Nordics must be brimming with genes. This does not make them safe from dangers, because "Hybrids do not breed true and by miscegenatic multiplication inferior variants would be thrown off and the superior race as a biological entity would lose its place in the evolutionary scramble. In short, exogamy indulged in by a more advanced people inevitably tends to impair the intrinsic quality of that people. About this there can be no dispute". These, and many other equally "indisputable" facts, are the basis of many pages of unbridled racism. Pages 148–178 are an antisemitic tract, complete with the story, "believed by the learned as well as the ignorant", that Jews used the blood of children of other races in their paschal celebrations, and the *Protocols of the Learned Elders of Zion*. The political conflicts and the Cold War are explained very simply: "Americans believe themselves to be in direct ideological opposition to the U.S.S.R. The impossibility of reconciliation between these two great Caucasoid powers arises from roots deeper than ideas or social forms. Large percentages of the peoples of both countries are non-Caucasoid and the racial ratio will change in each country, coloring the collective character and ethos of the populations. In this respect the evolutionary advantage undoubtedly lies with the U.S.S.R. Yet both powers, indeed the whole Caucasoid race, may in the end be beaten in the struggle to survive by the more stable and homogeneous Mongoloids". There is not even hope that the Caucasoid thoroughbreds can be preserved by emigration: "Despite the rapid progress now being made in cosmic rocketry the feasibility of transporting men in effective numbers to another planet or star could be ruled out as not being realizable in time". Here one is tempted to conclude—if mankind really is what the author says it is—that other planets ought not to be contaminated by it. THEODOSIUS DOBZHANSKY

WORKING ON ANIMALS

Methods of Animal Experimentation

Edited by William I. Gay. Vol. 1, pp. xv+382. 96*s*. 6*d*. Vol. 2, pp. xv+608. 148*s*. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1965.)

DR. GAY is to be congratulated on undertaking a task of considerable magnitude, knowing well that it would be impossible to achieve perfection at the first attempt. As chief of the Animal Resources Branch, Division of Research Facilities and Resources of the U.S. National Institutes of Health, he is in a particularly good position

to compile a book on methods of animal experimentation. He has, indeed, produced a most useful encyclopaedia.

With so much to praise, I also have a duty to criticize, in the sure hope that the second edition will correct whatever deficiencies detract from the first. A chapter on drug administration is sketchy and contains little of practical value. In the chapter on hibernation there is no mention of the work of Parkes, Smith and others of the National Institute for Medical Research, London, on freezing and recovering warm-blooded animals. There is no account of methods of measuring spontaneous activity, although there is an excellent chapter on controlled exercise. There is no account of methods of pyrogen testing. Most surprisingly, the reader will look long for instructions about how to make simple injections, and will eventually track down the information in a chapter on methods of infection. There is no description of methods of skin transplantation, nor of the replacement of haemopoietic tissue following whole body irradiation.

The arrangement of the chapters follows no obvious system, which makes these volumes less easy to refer to than they should be. The index, which is particularly important in such a valuable work of reference, is incomplete, misleading, and even inaccurate in places. Moreover, each volume has its own index. It would surely have been possible to have had a comprehensive index for both volumes reproduced at the end of each volume as is done in so many other two-volume works of reference. It would also have been better to have numbered the chapters serially from the beginning of Volume 1 to the end of Volume 2, and to have done the same thing with the pagination.

Of the twenty-three authors, twenty-two are shown to work in American laboratories, and one in a British laboratory. This results in an inevitable bias, because even to-day only a few workers are as familiar with the literature and methods foreign to their own country as they are with indigenous material. But in one or two chapters this process seems to have gone a little too far. In one, 35 per cent of the references are self-citations, and in another, 30 per cent. In a third, the author cites two of his own "unpublished observations".

Despite these remarks, the two volumes are a great contribution to the literature of biological methods. There is a tendency to-day for the newly qualified biologist to be turned loose on a problem of which he has no experience. He reads the literature, and is impatient to get on with his first series of experiments. But who is to teach him how to manipulate the subject of his experimental methods, namely, the living animal? This work is therefore not only a necessary bench book for every biologist who uses animals, but is also bound to assist in the humane treatment of animals under experiment.

The presentation of both volumes is consistent with the very high standard that we have come to expect from Academic Press. Unfortunately, the price of the two volumes together may deter some laboratories from buying them. I am quite unable to recommend such a false economy.

W. LANE-PETTER

CHANGE AND DECAY

Aging

Proceedings of the Symposium held at the University of Oregon Medical School, 1964. Edited by William Montagna. (Advances in Biology of Skin, Vol. 6.) Pp. xv + 273. (London and New York: Pergamon Press, 1965.) 100*s*. net.

Behavior, Aging and the Nervous System

Biological Determinants of Speed of Behavior and Its Changes with Age. Edited by A. T. Welford and James E. Birren. (A Monograph in The Bannerstone Division of American Lectures in Geriatrics and Gerontology.) Pp. xvi + 637. (Springfield, Ill.: Charles C. Thomas, 1965.) 22.50 dollars.

THESE volumes record the contributed papers—but not the discussions—of two symposia on ageing. At first sight they have little in common except in so far as they demonstrate how widely disparate subjects and interests can be included under the general heading of ageing research. Yet while the topics were obviously very different there is one common feature. The detailed semantic arguments about how to define ageing, which often seem to distract gerontologists and to divert them from their main business, were avoided and both meetings clearly got down straight away to the description of fresh experimental findings and the interpretation of results.

Advances in the Biology of Skin is the sixth of a series of reports of meetings devoted to the skin and is concerned solely with its ageing. The skin is, indeed, an organ that is very vulnerable to the accumulation of environmentally induced injuries during life and it is also much more complex and variable from site to site, both in structure and function, than is often imagined. In general, it shows an increasing disarray with increasing age together with a decreasing number of functioning units the individual activity and efficiency of which are declining. Oberste-Lehn, in a very detailed paper, however, suggests that there may be new growth of follicles, and while some receptor organs, for example touch corpuscles, get fewer, pacinian corpuscles are being constantly remodelled and others, like free nerve endings, seem to be little altered.

For many people, perhaps, ageing of the skin means primarily loss of or greying of hair and a wish for some way of rejuvenating the cosmetic appearance. Little information and less comfort are provided on the first topic, but the capacity of hormones to restore the character and the biochemical nature of the ageing skin is entered into very thoroughly.

In his paper about the changes in nerve endings in skin Winkelman begins by saying that "it is accepted that ageing dulls the senses but how this occurs has scarcely interested anyone but philosophers". The second book, *Behavior, Aging and the Nervous System*, shows that the psychologists at least are aware of the force of the criticism and accept the truth of the first statement. By and large the whole volume is devoted to providing psychological and physiological data from clinic and laboratory that are appropriate bases for discussions about the slowing of behavioural patterns with increasing age. Almost all the work mentioned has been carried out on human subjects and the occasional papers describing animal experimentation are not of particularly high quality.

There are many possible places in the nervous system where slowing of reaction patterns and of skilled performance or memory storage may be initiated—in the sensory organs, the conductor mechanisms, the central areas or in the effector systems, and both autonomic and voluntary nervous systems may be involved. All are considered in various degrees of detail and completeness. In addition, it is noteworthy and commendable how vigorously the participants faced up to the constant difficulty of deciding whether a change in function in old people is a "normal ageing change" or is a consequence of superimposed disease. They do this by considering the slowing of performance brought about by physical disease, whether local, as in brain injury, or general, as in cardiovascular disease, or by psychological disease, as in schizophrenia. Nor are practical problems forgotten. For example, how best to use and train older workers in industry and the ability of older airline pilots to make correct decisions when under load are both considered in some detail.

Neither of the books is cheap and it is unlikely that any one person will want to buy both. But without doubt, there is much more justification than usual for

publishing the proceedings of what were evidently, within their respective frameworks, interesting and illuminating meetings. P. L. KROHN

MUSIC AND PHYSICS

The Physics of Musical Sounds

By C. A. Taylor. (Applied Physics Guides.) Pp. xii+196+record. (London: The English Universities Press, Ltd., 1965.) 42*s*. 6*d*.

MUSIC is important to many of us, and sound is important to all but the deaf. Yet, as Prof. Taylor writes concerning his experience with budding physicists, "sound had been missed out and the problem of teaching it at a higher level became more challenging".

This book can serve for a useful undergraduate course in physics with an emphasis on sound and music. It contains neat, self-contained treatments of the wave equation, the vibration of strings, square membranes, and cylindrical and conical pipes, harmonic analysis, Fourier transforms, convolution, resonance, coupled systems and starting transients. Mathematical sections are indicated by an asterisk at the heading, so that the musician can skip them in reading the book. The purpose and general nature of the mathematics is clearly explained in the rest of the text.

On the musical side there are wise, if necessarily incomplete discussions of the nature of musical sound, hearing, sum and difference tones, scales, consonance and dissonance, and architectural acoustics. The theme of "the possibility of designing a completely new musical instrument" unifies the musical and the physical content of the book.

The book seems quite reliable. On page 39 it says "It is thus clear that the ear is insensitive to phase . . ." which contradicts some experimental results for steady tones[1] but conforms to traditional experiments. As Prof. Taylor notes in many places, our knowledge of acoustics, and especially of psychoacoustics and physiological acoustics, is small.

We may hope that the publication of *The Physics of Musical Sounds* will help to overcome the present neglect of acoustics. Other influences are at work. Advances in electronic instrumentation, and especially in digital computers, have given to-day's acousticians much more flexible and powerful tools than the ingenious optical and mechanical techniques on which Prof. Taylor dwells. Concerning experiment, the book is a good summing-up of what has gone before, and a useful source of references for musicians and physicists alike. But to-day techniques which are merely mentioned are pushing our knowledge of acoustics forward. J. R. PIERCE

TRAFFIC CONTROL

Traffic Control

Theory and Instrumentation. Edited by Thomas R. Horton. (Based on papers presented at the Interdisciplinary Clinic on Instrumentation Requirements for Traffic Control Systems, held December 16–17, 1963, at New York City.) Pp. xi+218. (New York: Plenum Press, 1965.) 12.50 dollars.

THIS book contains ten papers divided into two sections, "Traffic Control Instrumentation, Theory and Practice" and "Case Studies of Large-scale Integrated Traffic Control Systems", and provides a useful summary of American work on road traffic control, from both the theoretical and the practical point of view. It contains a very readable introduction and a useful short list of publications for the reader who wishes to go further. Most of the information has been published elsewhere, but it is very useful to have it collected in a single volume. The information on instruments is not too detailed, but is sufficient to show the principles of operation of devices for measuring the basic quantities required for control.

The fundamental relations between the three variables, flow, concentration and speed, are discussed in one paper, although no reference is made to the basic work of Lighthill and Whitham[1] in this field. Several theoretical models give relations between speed and concentration which are fairly close to observed results over most of the range, although they all tend to be unrealistic to a greater or lesser extent at low concentrations.

In order to design a traffic control scheme, one needs a judicious blend of theoretical analysis and practical engineering ability. On the whole the book brings out the need for both, although the relationship between them may not always seem clear. A theoretical approach which includes a large empirical element appears to have been the most successful one. The paper by D. L. Gerlough on simulation of traffic situations, using digital electronic computers, rightly points out that comparatively rough models can be adequate for making the required calculations. In most cases what is required is the effect on the overall travel time of a change in the control system. Travel time can be very susceptible to small changes in the flow of traffic, the types of vehicles, the presence of parked vehicles and a large number of other factors, not all of which can be fully controlled. It may seem to be desirable to allow precisely for all these effects, averaging out over the whole spectrum, but in practice it is sufficient to assume that conditions are uniform, at any rate during normal working hours. Conditions during peak periods are special and the traffic demand may be changing rapidly. Intersections in particular are frequently overloaded during peak hours and methods of minimizing delay under these conditions are discussed in an interesting paper by D. C. Gazis.

There is at present a great deal of interest in the central control of traffic signals by computer—two major schemes are being put in hand in West London and Glasgow. Methods of tackling such situations are given, and the experiment in Toronto, which was begun several years ago, is described with useful details of costs.

Some recent work at the Road Research Laboratory, using a computer programme which approximately minimizes total travel time in a network of signals, has been described by Hillier[2].

Another topic discussed is the control system for the Congress Expressway (an urban motorway) in Chicago. In this system congestion on the expressway at critical times is avoided by restricting the flow of traffic entering on a particular ramp. Assessment of the scheme has included measurements of the effects on traffic which finds an alternative route, and showed that during the whole peak period there was an average small reduction (2·5 per cent) in travel time.

SUNDIALS REVIVED

Les Cadrans Solaires

By R. R. J. Rohr. Pp. 208+4 colour plates. (Paris: Gauthier-Villars et Cie., 1965.) 58 F.

IN the preface to this book, Dr. Henri Michel, of the Academie Internationale de l'Histoire des Sciences, cites three essentials of a good book: to have something to say; to say it; and to say nothing else. These are well realized in Captain Rohr's treatment of his subject, the sundial in all its forms. Beyond this, he achieves a remarkable blend of the philosophical, historical, artistic and practical, thus appealing to a wide range of readers.

In his introduction, the author transmits his enthusiasm for all these aspects (and notes that he makes allowance for the non-mathematically minded by printing passages relating to calculations in smaller type) and acknowledges the help received from other specialists in his field.

The first of ten chapters traces the evolution of the sundial from Egypt in the fifteenth century B.C. to the heliochronometers used as late as the turn of this century by French railways to regulate the clocks at rural stations, and the modern elaborate ornamental dial. Chapter 2 covers the movement of the Earth, co-ordinates, equation of time and other factors to help the constructor of dials find the meridian and determine the orientation of walls.

Classical dials, in which the gnomon is fixed parallel to the Earth's axis of rotation, and inclined plane dials, such as those carved on the faces of polyhedrons, are dealt with in their major variations in two detailed chapters. The reader is then acquainted with the effects of changes in declination, the various reckonings of the day from sunrise to sunset, and the delineation of the tables of the dials. Chapter 6 deals with analemmatic dials, that is, those in which the gnomon is movable.

Although one may be surprised by the ground so far covered, these six chapters have only been concerned with what may be considered normal dials. Rohr now embarks on the rarer dials, including lunar dials, those by which the Sun's elevation above the horizon is measured and azimuthal dials which indicate time by means of the variation in the Sun's azimuth.

The penultimate chapter, complementary to the first, illustrates the evolution of the sundial by existing examples intended for public use. It is interesting to note that the earliest dial showing equal hours dates from 1493, all previously indicating temporal hours (that is, based on the ancient division of the day from sunrise to sunset).

Outstanding examples of the work of modern artists are noted, such as the armillary sphere at Phillips Academy, Massachusetts, and the most recent Swiss instruments which have an error of about 1 min.

For completeness the author concludes with some fifty inscriptions found on sundials (mainly offering advice of an improving nature) ranging from the plainly depressing to the distinctly hopeful. A neat anecdote rounds off the book.

Les Cadrans Solaires is a most informative and readable work, clearly printed on good paper, extremely well illustrated with a frontispiece in colour, 51 photographs and 105 figures. Appended, before a bibliography and index, are tables giving the conversion of time to arc, refraction, equation of time, the Sun's declination, hour angle and magnetic variation.

These are an obvious hint to move courageous readers to revive the ancient art of dialling. P. S. LAURIE

PHYSICS FOR SOPHOMORES

The Feynman Lectures on Physics

By Richard P. Feynman, Robert B. Leighton and Matthew Sands. Vol. 1: Pp. 530. 66*s*. Vol. 2: Pp. 540. 66*s*. Vol. 3: Pp. 375. 51*s*. (Reading, Mass., and London: Addison-Wesley Publishing Company, Inc., 1964 and 1965.)

WHAT to include in the undergraduate course, and how best to teach and stimulate the student, whether by lectures, tutorials, seminars or practical classes, are questions which face every university physics teacher. There are no ready answers. A lecturer may succeed because of his personality, the novelty of his subject, his impressive demonstrations or showmanship, or merely because of his adaptability to his audience. Advances and discoveries made in the research laboratories are very rapidly publicized these days through the medium of the Press, radio or television, and often they are presented in a most elegant and convincing manner. The student becomes aware of these advances long before they can be incorporated into the material of his course. The enthusiastic and bright school-leaver complains that the course is dull and old-fashioned; he expresses boredom and frustration. Nevertheless, it is important to direct his attention to fundamentals and to the avoidance of elaborate and sometimes involved mathematical treatments of physical phenomena, in the introductory stages of his course. He must prepare himself to be receptive of new ideas and concepts and future developments and to judge their applicability and soundness on the basis of previous knowledge and fundamentally established principles. He must try to avoid cluttering up his mind with the rapidly growing and vast number of present-day achievements and applications in physics and technology, however exciting they may seem to be when first met. There is no doubt that undergraduate physics courses need to be altered to meet the challenge of modern requirements. Physics teaching and syllabuses at the "O" and "A" levels are now being remodelled, but the link has yet to be forged between the new school physics and the university introductory course.

At the California Institute of Technology the development of such an introductory course began some five years ago under the supervision of Profs. R. B. Leighton, H. V. Neher and M. Sands. Prof. R. P. Feynman, who had been giving the two-year sophomore lectures, agreed at Sands's suggestion to revise his course and with the help of his colleagues to deliver a set of lectures specially devised and addressed mainly to the more intelligent and actively minded of the students. The needs of the less able students were not to be overlooked; they would be provided in the lectures with a backbone of material. And what Feynman calls the "extra fireworks", included in the lectures, would be presented in such a way that no student would be made nervous. The sequence would not be traditional, and topics not usually found in such courses would be included.

The lectures Feynman gave were tape-recorded, edited carefully and to some extent re-arranged. The three volumes of *The Feynman Lectures on Physics* are the final result. They are not text-books, though in some respects they come very close to being such. The text retains the easy flow of language used by the lecturer; illustrations are brought in unhesitatingly from other parts of physics not yet discussed to clarify some new step or application; and always the emphasis is on the simple underlying physical principles.

Volume 1 contains the lectures given in the first year. Its fifty-two chapters cover mechanics, relativity, geometrical and physical optics, the kinetic theory of gases, the principles of statistical mechanics, thermodynamics, sound and waves, and symmetry in physical laws. It was to be expected that Feynman would want to include as early as possible the concepts of quantum physics, and Chapters 37 and 38 on quantum behaviour and the relationship between waves and particles represent the talks on these subjects which were introduced before dealing with the kinetic theory of gases. The more formal treatment of quantum mechanics was postponed until later in the course.

Volume 2 is based on the lectures given in the second year. These consisted mainly of electricity and magnetism, and the account printed in Volume 2 is a strongly revised, expanded and re-arranged treatment of the lecture material. The differential calculus of vector fields was discussed first, enabling the subsequent electromagnetic field theory to be dealt with in rigorous mathematical form, using vectors and tensors. In addition to electricity and magnetism, the geometry of crystals and crystal growth, elasticity and elastic materials, and fluid flow, are also discussed in Volume 2. Feynman, in his preface, mentions that he was satisfied with his first-year lectures, but was

unhappy about those on electricity and magnetism. His complaint is that he failed to discover a unique or different way of presenting the subject from that usually followed. The lengthy mathematical discussions needed to deal with electromagnetic phenomena may indeed worry the student as he looks through Volume 2 and considers that he must absorb the contents together with many other topics during his all-too-short academic course.

Twelve lectures at the end of the second year were devoted to quantum mechanics, but these were later supplemented by seven additional lectures in May 1964. By reprinting Chapters 37 and 38 of Volume 1 as the first two chapters of the third volume and adding the edited version of the quantum mechanics lectures, Volume 3 is a self-contained unit relatively independent of the other two volumes. Following the initial statement of quantum behaviour, probability amplitudes, spin and one-state systems are discussed. The ammonia maser is used to introduce the consideration of two-state systems, and then the propagation of electrons in crystals, semiconductors, symmetry and conservation laws, and the quantum mechanics of angular momentum are dealt with. The volume concludes its introduction to quantum mechanics by a treatment of the Schrödinger wave equation and its solution in the case of the hydrogen atom.

Feynman was well aware that the best teaching can be done only when there is a direct individual relationship between student and teacher. His lectures suffered because there was little or no feedback from the audience to the lecturer, but he puts forward the excuse that when to-day there are so many students to teach there must be some substitute for the ideal, and he expresses the hope that his lectures and subsequent text will meet the present need. Lecturers in universities and technical colleges will be grateful for the experiment he made, and for the record that they can study in detail. The *Lectures* provide a first-rate background for the further study of physics, and an excellent guide to the preparation of lectures which will capture and maintain the interest of students with the obvious success and enjoyment that Feynman's achieved.

S. WEINTROUB

MODERN ELECTROCHEMISTRY

Treatise on Electrochemistry

By G. Kortüm. Second, completely revised Englih edition. Pp. xxii+637. (Amsterdam, London and New York: Elsevier Publishing Company, 1965.) 170*s*.

THE previous English edition of Prof. Kortüm's *Treatise on Electrochemistry* (1951) was a two-volume work, based on the first German edition (1948), but with a great deal of additional material added by J. O'M. Bockris, including chapters on experimental techniques in electrochemistry, numerical examples for the student and tables of electrochemical data. The volume under review is a new translation of the third German edition (1962), with some modifications to bring it up to date. It does not include the additional material of the first English edition, and thereby regains the unity of the German text. The translation is adequate but inelegant, and the literal translation of German words often produces terms which will be unfamiliar to the English-speaking reader, for example 'fertility' and 'influence constant' (in electrostatics), and 'first and last heats of solution'. Occasionally this leads to mis-translations such as 'prüfen' as 'prove' and 'eventuell' as 'eventually'.

The first three chapters are introductory in character, and could well have been shortened considerably, or even omitted altogether, in a book of this nature. Chapter 1 contains much elementary electricity and magnetism, such as Ohm's law, Gauss's theorem, the Poisson equation, etc., all worked through in detail. Chapter 2 works through thermodynamics from scratch in a straightforward but somewhat old-fashioned way, based on the Carnot cycle. Chapter 3 is entitled "The Solution of Ions", but includes discussions of polar and non-polar bonding, and detailed accounts of different types of molecular interaction, of lattice energies, and of the theory of liquid dielectrics, all with a good deal of algebra. These three chapters occupy nearly one-quarter of the book, and contain little which could not be found in general treatises on physical chemistry.

Chapters 4–9 deal with the usual topics of classical electrochemistry, such as strong and weak electrolytes, ionic interaction, and the theory and applications of conductance and e.m.f. measurements. The exposition and choice of material are excellent, and (as throughout the book) there are copious references to general articles and original papers. A few sections have not been brought fully up to date: thus three pages are devoted to the quinhydrone and antimony electrodes but only one to the glass electrode; the section on dissociation of acids in deuterium oxide gives no references later than 1938; and the kinetic salt effect is not related to transition state theory.

The final three chapters, comprising more than one-third of the book, represent its most valuable contribution. Topics treated include potential differences at phase boundaries, over-potential, electrode kinetics, corrosion and passivity, and polarography and other electrochemical analytical techniques. These chapters are truly up to date, and the author provides a welcome guide to the confusing variety of facts and theories in controversial fields such as electrode polarization. There is much interesting information about practical applications in fields such as electrometallurgy, fuel cells and ion-exchange resins, and attention is drawn to many important theoretical and practical problems which remain unsolved.

To sum up, this book contains much of value to research workers in the field of electrolytes and to advanced students of physical chemistry, though it could have been made more digestible (and cheaper) by abbreviating the earlier sections. It should certainly be in any well-stocked chemical library.

R. P. BELL

HOT GLASS

Structural Transformations in Glasses at High Temperatures

Edited by N. A. Toropov and E. A. Porai-Koshits. Authorized translation from the Russian by E. B. Uvarov. (The Structure of Glass, Vol. 5.) Pp. ix+223. (New York: Consultants Bureau, 1965.) 25 dollars.

STUDIES in the field of glass technology and the chemistry and physics of the silicates have been very active in the U.S.S.R. for some considerable time. In recent years four All-Union conferences on the glassy state have been held and the Consultants Bureau has made available translations of the proceedings of these conferences. This is a very useful service, particularly as some of the volumes have been published in translation almost simultaneously with their appearance in Russian.

Volume 3, which formed the proceedings of the fourth All-Union conference on the glassy state, was sub-titled "Catalysed Crystallisation of Glass". This showed that a very considerable effort was being placed in the U.S.S.R. on the development of the glass-ceramics, introduced in the late 1950's as "pyrocerams" by Corning Glass Works. *Structural Transformations in Glasses at High Temperatures*, published only one year later, shows that this effort is not being relaxed at all. Although the title is different, with one exception the papers in the present volume are also concerned with nucleation and crystal growth, an understanding of which is a necessary background for the development of successful glass ceramics.

The problem of nucleation is considered by V. N. Filipovich by discussing a very simple model of a mixture of two particles. As he says, " . . . success depends on the extent to which the model reflects the real system. The development of a detailed theory of crystallization of complex glasses and melts directly depends on the state of the theory of liquid and glass structure, which is still far from perfection".

The editor of this volume, E. A. Porai-Koshits, has made important contributions to the study of glasses by X-ray diffraction and his laboratory has for some years now concentrated on the use of small-angle X-ray diffraction, light scattering and electron microscopy to study the development of immiscibility in simple glasses and the initiation of crystallization. This experimental work is of a high standard and very useful data on microphase separation in lithium oxide and sodium oxide silica glasses are included.

In the third volume most of the work was concentrated on glasses in the Li_2O–Al_2O_3–SiO_2 system and some papers on crystallization in this system are included in the present volume. In addition glasses containing sodium oxide in place of lithium and/or gallium oxide in place of alumina have been examined. In the alkali aluminosilicate glasses, the devitrification products retain the alumina in the anionic framework, but the gallium glasses give only crystals in which the anionic framework appears entirely of silica.

Work by Toropov and his co-workers on the MgO–FeO–SiO_2 system shows that thought is still being given to the production of useful ceramic materials from blast furnace slags.

There is a little overlap with the previous volume particularly in the theoretical section and space could have been saved by editorial action; for example, the same argument and the same diagram are repeated on pages 35 and 40. The appearance of this volume so soon after the previous one shows very definitely that these new materials are considered to be of great importance in the U.S.S.R.

R. W. DOUGLAS

UNCERTAIN MATERIAL

Radiation Damage in Graphite

By J. H. W. Simmons. (International Series of Monographs in Nuclear Energy, Vol. 102.) Pp. xii+242+8 plates. (London and New York: Pergamon Press, 1965.) 80*s*. net.

Radiation Damage in Graphite will be of great value to those who are concerned with the effects of reactor irradiation on the properties of graphite and particularly to those whose interest arises from practical reactor problems. The introductory chapter is followed by a clear account of the physical processes in which the atoms are involved during radiation and a description of the defects which are produced. This is followed by four chapters which describe, in turn, the behaviour of electrical and mechanical properties, thermal and structural properties, the dimensional changes and the mechanical properties. Finally, a full account is given of stored energy effects and the way in which this can be measured and of the phenomena of radiation annealing. Particularly impressive is the series of excellent photographic plates which provide visual evidence of the radiation damage, notably as seen in the electron microscope.

To one who was concerned with the early investigations of this subject it comes as rather a shock to see how ill-defined many of the concepts still are. A reader approaching the subject for the first time might well be confused by the mass of data which is available but which, because of the heterogeneity of the radiation and the complications of the damage processes, is very incompletely digested. In assessing this, one is left with much doubt, and certainly no information, about the reliability of some of the experimental results, in a field in which reproducibility is not to be taken for granted. Figs. 45, 56 and 81 provide typical examples of justifiable doubts concerning the data. The theoretical calculations seem to be similarly fraught with difficulties, and it is no surprise to find a note added in proof which, concerning the displacement energy T_d, says "It now appears that 60 eV is a better value than 25 eV, and if this is accepted, the number of displaced atoms given in this book should be reduced by the ratio 25 : 60".

The author has achieved a very creditable performance with his cast of eccentrics and has provided a valuable, up-to-date story of his field.

G. E. BACON

EXPERIMENT SIZE IN INDUSTRY

Sample-Size Determination

By Arthur E. Mace. Pp. x+226. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1964.) 96*s*.

THE title of *Sample-Size Determination* is extremely misleading, suggesting as it does a treatment of an important problem in the design of surveys. The book is, in fact, "a compilation of mathematical procedures for determining the optimum size of a research experiment" and is concerned exclusively with industrial experimentation.

The heart of the book is contained in Chapters 5–7. The first of these is devoted to the estimation of confidence limits for parameters of normal, binomial, and exponential distributions. Each problem is discussed in a separate section, which begins with an introduction, in which the relevant statistic is described, its distributional properties are stated, and a formula is given for determining the degree of replication required to achieve a confidence interval of specified width; this is followed by an example, and a postscript (a good feature) discussing the robustness of the sampling distributions involved. The examples are presented, in monotonously stereotyped form, as little stories, the hero of which is an engineer ("An engineer wishes to estimate the mean change in resistance of a certain type of 3-Kohm resistor during the first 1,000 hours of a life test"), who usually has to deal with some rather well-informed manufacturers ("The manufacturer . . claims that knowing the initial resistance value of an individual specimen he would be able to predict the tolerance range for resistance of this specimen after 1,000 hours to within 120 ohms"), and who after a certain amount of arithmetic, laid out in considerable (at times unnecessary) detail, arrives at a happy ending in the form of a conclusion ("Therefore, the engineer concluded that a sample of 46 specimens of the resistor type should be placed on test").

Chapter 6 is similar in character to Chapter 5, except that it presents its problems in terms of hypothesis testing, with control of errors of the second kind, and Chapter 7 deals with problems of selection.

The examples in these chapters could provide quite a useful 'cook-book' for a reader prepared to tolerate the 'child's guide' flavour of the presentation (though I hope no experimenter would be perverse enough to do an experiment consisting of 160 identical half-replicates of a 2^3 factorial design, as suggested in one example!). The introductions to the examples are unfortunately much less satisfactory. The author's attempt to make each section self-contained has involved him in much unnecessary repetition, while many of these sections are far too condensed to mean much to the sort of reader who needs to have examples spelled out in the detail given here; the writing also is not always as clear as it might be. These criticisms, and especially the last, apply also to the first four (short) chapters, intended to provide a logical founda-

tion for Chapters 5–7. These are written in terms of the utmost generality, with no examples, and contain a number of sentences at the exact meaning of which I can only guess.

I noticed errors in two formulae. In the equation at the foot of page 69 the term $p_0^n/(n-1)$ should be p_0^n/n, and (more seriously) in the formula for f on page 82 the complete numerator of the fraction should be, but is not, squared.

The book is completed by four chapters on sequential sampling, lot acceptance sampling plans (illustrated by discussion of two U.S. Defense Department Military Standards), sample-size precision schedules, and decision functions, a three-page bibliography, and a useful 28-page appendix of tables. The tables are photographically reproduced, with results that though always legible are sometimes unattractive: this detracts from the otherwise high standard of production.

Perhaps this book can best be summed up as a cook-book with pretensions: as such it is expensive at the price.

M. R. SAMPFORD

General Protozoology

By V. A. Dogiel. Revised by J. I. Poljanskij and E. M. Chejsin. Second edition. Pp. xiv+747. (Oxford: Clarendon Press; London: Oxford University Press, 1965.) 147*s*. net.

A NEW text-book devoted to the general aspects of protozoology has been greatly needed, as the classical books of the past (Doflein, Wenyon, Calkins, etc.) have become much out of date. Included in the latter was the *General Protozoology* of Dogiel, published in 1951 in Russian. It has now been practically rewritten by two of his students, J. I. Poljanskij and E. M. Chejsin, from the Institute of Cytology, Leningrad, and well translated into English by C. A. Hoare. It will prove invaluable to protozoologists and biologists in general; on account of the lucid exposition of the main features of the protozoa, with particular reference to their morphology, cell-division and evolution. Chapters are accordingly devoted to the cytoplasm, nucleus, skeletal and fibrillar structures, organelles of locomotion, methods of reproduction and regeneration, and evolution. The physiology of the organisms, including metabolism and irritability, are considered separately, while there are two special chapters on life-cycles and ecology. Examples are taken from the free-living and parasitic protozoa, but there is, of course, no detailed treatment of individual species, and medical and veterinary protozoology, as such, is entirely omitted from consideration. This book provides the fundamental background to a subject which is advancing so rapidly, particularly in the elucidation of fine structure, genetics and metabolism, that still another edition will be required in a few years' time. Readers will find it stimulating and challenging; in many places, it is emphasized that the "problem leaves much to be investigated" and this recommendation applies as much to fundamental phenomena of biology as to host–parasite relationships, systematics and other questions of more specialized interest. The book is illustrated with 326 figures of exceptional clarity and its references are thoroughly international.

P. C. C. GARNHAM

Biophysics and Cybernetic Systems

Edited by Myles Maxfield, Arthur Callahan and Lawrence J. Fogel. (Proceedings of the Second Cybernetic Sciences Symposium, October 13, 1964.) Pp. vii+184. (Washington, D.C.: Spartan Books, Inc.; London: Macmillan and Co., Ltd., 1965.) 45*s*. net.

INTENDING readers would be well advised to begin with this book at the Appendix. The conference of Californian scientists which it reports is one of the many cross-disciplinary explorations that seem nowadays to find eager publishers, and the Appendix contains a candid and not altogether flattering debate as to its value. The time must surely come soon when "quality control" will be applied to papers for symposium volumes as for those in reputable journals, and publishers who neglect to do so will become known accordingly.

It is not suggested that all or even most of the papers here presented fall short by journal standards. The subjects range from the biophysics of natural and synthetic membranes to the modelling of complex biological processes and the theory of artificial intelligence, and almost all the material will be of some interest to specialists in the respective fields. Most original and stimulating, perhaps, is L. J. Fogel's discussion of "Artificial Intelligence through a Simulation of Evolution". He proposes a method of allowing an automaton to evolve its own logic by a search process of "natural selection" which he considers to have reasonable prospects of convergence. In a different direction R. L. Binggeli's finding, that pigeons improve in left–right discrimination when they lose one optic tectum, throws intriguing light on the functional significance of brain symmetry.

But a good many of the reports here presented—especially in the field of network-modelling—are acknowledged to be preliminary or inconclusive. In a research meeting of specialists this may be positively beneficial to the freedom and vigour of discussion. Whether it justifies their addition in that form to world literature is another question.

D. M. MACKAY

Vistas in Astronomy

Edited by Arthur Beer. Vol. 6: Celestial Mechanics, Instrumentation, Meridian Astronomy, Solar Research, Astrophysics. Pp. vii+214. (London and New York: Pergamon Press, 1965.) 84*s*. net.

THIS is the sixth volume in a series containing sets of review papers on subjects covering all the fields of astronomy and astrophysics, written by internationally recognized specialists. The volume includes seven such papers by eight scientists, working in six different countries.

Of particular interest is the paper on relativistic theories of gravitation by G. J. Whitrow and G. E. Morduch, in which one finds an extensive comparison of the effects predicted by the general relativity and eight Lorentz-invariant theories of gravitation for the three astronomical tests of relativity: the deflexion of a light-ray near a mass; the gravitational red-shift; and the advance of perihelion in the two-body problem. Additional advances of perihelion and node due to the rotation of the central body are also considered. None of the theories are strictly equivalent to the general relativity in their predicted effects. The final conclusions are particularly well presented and can be read fruitfully without going through all the mathematics.

Another interesting article is that on the diffuse emission nebulae by S. R. Pottasch. The problems of structure, brightness and interpretation of their spectra are very clearly presented in a broad review of all data concerning these important members of our Galaxy.

The other papers are: one on catalogues of meridian observations of stars (F. Schmeidler); two on optical and seeing problems of long-focus refractors (P. A. Ianna and S. L. Lippincott); and two on active regions of the Sun (S. B. Pikelner and J. Kleczek). All, without doubt, will be quoted frequently in future works and constitute an important contribution in their respective fields.

J. KOVALEVSKY

MEETINGS

THE MEASURE OF THE MOON

AFTER many decades spent in astronomical semi-obscurity, the Moon has emerged to claim renewed interest. The reasons for this are of historical significance. From time immemorial, astronomy has been debarred from the status of a genuine experimental science by the remoteness of its objects of study. With the exceptions of the meteors intercepted by the Earth, the properties of all celestial bodies could be studied only at a distance—from the effects of attraction exerted by their mass, and from the ciphered message of the light brought by nimble-footed photons across the intervening gaps of space. The dramatic emergence of long-range spacecraft in recent years promises to change this picture.

It was against this background that an international conference on selenodesy met at the University of Manchester between May 30 and June 4, under the joint sponsorship of the Department of Astronomy and of the Terrestrial Sciences Laboratory, U.S. Air Force Cambridge Research Center. Mahlon S. Hunt of the Terrestrial Science Laboratory and I were joint chairmen. The aim of the conference was to bring into focus our knowledge of the motion of the Moon about its centre of gravity, its shape and gravitational field, and the large-scale topography of its surface. More than forty scientists from thirteen countries (Algeria, Austria, Egypt, France, Greece, Holland, India, Italy, Japan, Poland, South Africa, the United Kingdom and the United States of America) congregated at Manchester.

The first day of the conference was devoted to a discussion of the problems of lunar librations (underlying all determinations of the shape of the Moon by stereoscopic methods). Prof. Karol Koziel of Krakow University surveyed present knowledge, based very largely on visual heliometric observations of the past hundred years—a necessary time baseline for studies of long-period terms. Such measurements represented the pinnacle of precision astrometry: their masters all belong to the past, for surprisingly few contributions to these studies have been made by photography even if it has been necessary to await the development of electronic computers to make full use of them. Prof. Koziel, together with Drs. Maslowski and Mietelski of Krakow Observatory, recently performed such computations at the University of Manchester, and their results were presented at the conference for the first time. The most significant establish a free libration of the Moon in longitude, suggesting that (to this extent) the Moon behaves like a rigid body. The elastic parameters of the lunar globe have not yet been introduced explicitly into the equations of the problem, and a determination of their values represents important scope for future work.

Further contributions to the general problem of libration of the Moon and other planetary satellites were made by Prof. Colombo of the University of Padua, and Dr. D. H. Eckhardt of the Cambridge Air Force Research Laboratories in the United States, who succeeded to a remarkable extent in making automatic the solution of the entire problem.

The second day of the conference was devoted to a survey of observational methods and techniques. Prof. Jean Rosch of the University of Paris reviewed the principal methods of observation from the days of Bessel to the present and emphasized the effects of atmospheric disturbances on the accuracy of the measurements. The highlights of this session were the contributions by Drs. R. Julian, Aerospace Division of Hughes Aircraft Company, Los Angeles, and M. Orszag, Centre Nationale des Recherches Spatiales, Paris, on the proposed methods for exploration of large-scale lunar topography by means of nano-second (ruby) laser flashes whose optical echoes can be timed so precisely as to measure the instantaneous slant range between the transmitter and the reflecting segment of the lunar surface with an accuracy of the order of 100 metres.

The third day of the conference opened with introductory addresses by Prof. J. Hopmann of the University of Vienna and Dr. Constantine L. Goudas, Boeing Scientific Research Laboratories, Seattle, Washington, who summarized present knowledge of the form of the lunar globe, based on observations made from the Earth. Extensive investigations have revealed that, within an error of a few kilometres in altitude, the Moon is essentially a sphere of mean radius 1,738 km. However, the departures of the actual lunar surface from such a sphere appear to be quite complex and can only be adequately represented by several tesseral harmonic terms of increasing order, of which numerically the most important appear to be those of fourth order. A mere ellipsoid certainly does not seem to represent a better approximation to the actual shape of the Moon than a mean sphere.

Determining the positions and altitudes of the underlying selenodetic control points from the Earth is one of the most exacting tasks of photographic astrometry, which can be successfully approached only by sequential photography with the aid of long-focus telescopes; these alone can enable us to eliminate the effects of imperfect quality of "seeing". Their use in turn calls for a massive effort which can be mounted only with well-equipped and large groups of investigators. The two principal groups of recent contributors to this field—the Aeronautical Chart and Information Center of the U.S. Air Force in St. Louis, Missouri, and the U.S. Army Map Service in Washington, D.C.—were represented at the conference by R. W. Carder and D. Meyer for the Air Force, and A. Nowicki for the Army, with additional contributions by Dr. G. A. Mills and M. D. Davidson of the University of Manchester.

The gravitational field of the Moon is not uniquely determined by the shape of its surface (which represents only a "boundary condition" of the dynamical problem). Nevertheless, it is probable that all conspicuous harmonic terms in the description of the geometry of the lunar surface will have similar counterparts in the exterior potential of the lunar globe. Important papers on the motion of the artificial satellites in the gravitational field of the Moon and on the converse problem of its specification from an analysis of satellite orbit perturbations were presented at the conference by Prof. W. M. Kaula of the University of California in Los Angeles (*in absentia*) and Dr. J. Lorell of the Jet Propulsion Laboratory of the California Institute of Technology.

The fourth and last day of the conference was devoted to the problems of local topography of the lunar surface. Prof. M. J. G. Minnaert of the University of Utrecht summarized in his introductory address the photometric methods which can be used for this purpose and emphasized the reduction of photographic data secured by the *Ranger* or *Orbiter* spacecraft. Following Minnaert's masterly exposition of his subject, J. Sasser of the NASA Manned Space Flight Center in Houston outlined the plans of the National Aeronautics and Space Administration for mapping the lunar surface in quest of *Apollo* landing sites; the afternoon session was largely devoted to an exposition (by Z. Kopal, T. W. Rackham, M. T. Jones, A. Rifaat and P. V. Sudbury) of the photographic methods for lunar mapping which have been developed at the University of Manchester in the course of the past seven years.

What have been the principal features of the present state of selenodesy which have emerged from the recent Manchester meetings? First, that it is inexpedient to undertake new extensive measurements of lunar librations, for there would scarcely be time to reap their harvest in the pre-*Apollo* era; once men have installed zenith telescopes on the lunar surface all Earth-bound observations of lunar librations will become obsolescent. On the other

hand, a clear need exists to reduce again existing observations on the basis of Eulerian equations, taking account of the finite elasticity of the lunar globe, and to develop their solutions to a greater accuracy than has been done so far, for much smaller librations than those perceptible from the Earth should soon become observable from the lunar orbiting satellites.

The observations to determine the lunar figure from the distance of the Earth can be tackled successfully only by experienced groups of investigators utilizing extensive series of sequential photography. The law of diminishing returns is clearly operative here, yet the current effort cannot be relaxed, because in this particular field a closer proximity to the object of the study is not necessarily an asset. In the future, optical echoes of laser pulses should represent the royal road to the problem, but at present these are not even around the corner.

There are many ways in which lunar shadow techniques to determine local topography of the Moon can be pushed further (for example, by a resort to over-exposed terminator photography) to yield resolutions of only a few metres difference in altitude, but there is no doubt that massive contributions of data from spacecraft will have to be handled largely by the automated photometric methods.

ZDENĚK KOPAL

COMPUTERS IN LIBRARIES

By Our Own Correspondent

THE view that the large libraries of the world should now move forward to use computers in managing their affairs is one of the general conclusions of the Anglo-American Conference on Mechanization of Library Services held at Oxford during June 30–July 3. A parallel theme running through the proceedings of the conference was that the large libraries should put their heads together to work out common standards and to pool their individual solutions to common problems. Neither librarians nor computer engineers at any time suggested that readers should be in any way restricted in the use made of libraries for the sake of easier mechanization. Indeed, it would appear that librarians feel as strongly about the principle that readers should not be told what to read as do doctors about the Hippocratic Oath.

The conference, which was attended by some sixty librarians and computer engineers from the United Kingdom and the United States, was a natural sequel to a number of exploratory discussions held in the past year or so between the principal libraries in the two countries. The chairman was Sir Frank Francis, director and principal librarian of the British Museum. Most of the meetings were held in the Curator's Room at the Bodleian, across the quadrangle from the dramatically restored seventeenth century façade above the entrance to the Divinity School.

The problems of British libraries, apparently shared by the Library of Congress and the University Libraries of Harvard and Yale, were described at the beginning of the conference by representatives from the British Museum, the Bodleian and Cambridge. At each place there is a large central library with a number of dependent institutions. At each of the British libraries the collection is ancient and the maintenance of the catalogue is a continuing problem. The rate of acquisition is high, not only because of the demands of scholars, but also because of the shower of books and papers descending on all copyright depository libraries.

The university libraries in particular are anxious to create union catalogues that will enable readers to know what books are stored at dependent libraries, in university departments for example, as well as centrally. This implies that it would be desirable to acquire and catalogue books and papers centrally. Steps in this direction are being taken by the Radcliffe Science Library in Oxford and by the Science Library at Cambridge. The Oxford project will yield a catalogue of scientific periodicals on magnetic tape and eventually in print as well, but this is counted as a pilot experiment. At all three British libraries, thought is being given to the mechanization of the catalogue in its entirety—a task which is made less formidable at the Bodleian by the fact that the existing catalogue of books acquired before 1920 has in any case to be redone.

Some of the advantages, and some of the accompanying problems, of mechanizing an existing catalogue were described at the conference by Mr. Foster M. Palmer, associate University librarian for reference and circulation at Harvard. A project to put on tape the shelf list at the Widener Library was begun some years ago. One product is a printed catalogue of parts of the library. Another is the facility which now exists for searching through masses of information about the books at Harvard for statistical analyses. Mr. Palmer thought that costs at Harvard so far worked out at 25 cents for a catalogue entry, but other librarians offered estimates both lower and higher than this. In producing a mechanized catalogue, the cost of computer time appears to be small compared with that of manual labour involved.

The British Museum is perhaps more aware than any other library of the difficulties of devising mechanized catalogues. Mr. A. M. Cain and Mr. J. W. Jolliffe, of the Department of Printed Books at the Museum, described some of the alphabetical problems which impede the use of mechanization. How best, for example, to deal with books whose titles are in Punjabi or Tamil. Transliteration is not a practical proposition, chiefly because of the difficulty of making a one-to-one correspondence between an outlandish language and its equivalent. This view was given powerful support at the conference by Bodley's librarian, Mr. R. Shackleton, who said that scholars would not be satisfied with anything but the best. The systems team at the British Museum under Mr. Cain has apparently recommended that in future the general catalogue at the Museum should use only Roman, Greek, Cyrillic, Slavonic and Hebrew, with Irish as well for output, and that transliteration into one or other of these should be attempted. But everybody seemed to agree that there are great and growing problems in dealing with the proliferation of individual languages and alphabets in south-east Asia. For computer engineers this means that the task of cataloguing a large library has to be conducted with an alphabet which may for practical purposes have as many as a thousand characters, when provision is made for numbers and for capital letters and punctuation marks.

How is all this to be done? Mrs. Barbara Evans Markuson of the Information Systems Office of the Library of Congress described the work being done in Washington to standardize the production of catalogues. American practice has for several years been simplified by the way in which the Library of Congress classifies and catalogues all books published in the United States in such a way that local librarians anywhere in the United States can obtain a standard catalogue card to go with each new acquisition. The importance of this service can be estimated by the statement of one delegate at the conference that the seventy-odd libraries affiliated to the Association of Research Libraries in the United States are reconciled to spending 18 million dollars a year on the maintenance of catalogues. What is now being done at the Library of Congress is to carry out this cataloguing operation by computer. Work on a small system called 'Project *MAR'C* has been running for some months which will produce a catalogue record of books currently acquired by one part of the Library. Magnetic tapes carrying this information will then be distributed to libraries elsewhere in the United States which will be chosen for their diversity. Librarians will be able to use the tapes for constructing their own

catalogues and for keeping themselves informed of the developing pattern of acquisitions at Washington.

Mrs. Markuson appeared to have been overwhelmed and even surprised to find that even more ambitious plans for mechanizing the Library of Congress have recently been welcomed by those who hold the pursestrings in Washington. Evidently the prospect is not unreal of a complete automation of cataloguing at the Library of Congress and, by extension, of other American libraries as well. Yet it is plain that much remains to be done before it will be known for certain how much information about a book should be included in the bibliographic record. This, it would seem, is one of the most fruitful fields for international collaboration and agreement, and Mrs. Markuson was eloquent about its urgency. Some librarians present were so mistrustful of the necessarily subjective process of constructing a description of a book that they were inclined to think that nothing but the title page would be a sufficient record.

The computer engineers are clearly aware of all these subtleties. Indeed, the undertone of the conference was that it would necessarily be a long time before enough work had been done to know how quickly and how completely libraries would be mechanized. Yet there is more than cataloguing in prospect. Some engineers talk of how computers will help with keeping records of borrowings from a library, how they could help with finding books scattered through several libraries dependent on a central institution, and how eventually they might also allow librarians to keep track of the frequency with which books are used so as to be able to arrange more adequately their stocks for the convenience of the readers. All this is also linked with the possibility that systems for transmitting information from one library to another may help enormously with the sharing of stocks, or at least with the sharing of experience. And nobody knows, of course, what will not happen when the books are on tape as well as the catalogues.

OBITUARIES

William Henry Eccles

W. H. ECCLES, who died on April 29, 1966, at the age of ninety, was a physicist who tackled with notable success some of the early scientific problems associated with radio communication. He was an adviser to both the Army and the Navy during the First World War, and later was directly associated with the development of world-wide wireless telegraphy and telephony, including the beginning of broadcasting.

William Henry Eccles was born at Ulverston, Lancashire. He went from a secondary school to the Royal College of Science at South Kensington, from which he graduated in 1898. The following year he joined Marconi in the laboratory of the Wireless Telegraphy and Signal Company at Chelmsford, where he investigated electrical oscillations in coupled circuits. His study of coherers led to results which were presented in his D.Sc. thesis in 1901.

Shortly afterwards he was appointed head of the Department of Mathematics and Physics at the South-western Polytechnic, Chelsea, and 10 years later he was reader in graphics at University College, London. In 1916 he became professor of applied physics and electrical engineering at the City and Guilds of London Technical College, Finsbury. It was during these early years that Dr. Eccles made his principal contributions to radio research. His work on coherers was continued in a comprehensive study of crystal detectors for radio reception, and in 1912 he presented a paper to the Royal Society expanding the theory put forward some years earlier by Oliver Heaviside to explain the propagation of radio-waves around the Earth by reflexion in the ionized conducting regions of the upper atmosphere. He suggested that the ionizing influence of the Sun's radiation would account for the observed differences in wave propagation by day and by night. During 1912–13 Eccles played a leading part in the British Association's investigations into the characteristics of atmospheric disturbances in radio reception. His book on *Wireless Telegraphy and Telephony*, of which the second and enlarged edition was published in 1918, was for many years one of the very few comprehensive text-books on the subject. *Continuous Wave Wireless Telegraphy*, published in 1921, was a pioneer work of reference in this subject.

Eccles's interest in electrical science and engineering was wide. He was president of the Institution of Electrical Engineers in the 1926–27 session, president of the Physical Society in 1928–30, and of the Institute of Physics from 1929 until 1931. He was keenly interested in the activities of the radio amateur, and was a founder member of the Radio Society of Great Britain and its president for 1923–24. R. L. SMITH-ROSE

Prof. F. Y. Henderson

THE death occurred on April 9 of Prof. F. Y. Henderson only 6 years after his retirement as director of the Forest Products Research Laboratory. Born in 1894, he was educated at the High School, Glasgow, and at the University of Glasgow, where he gained the Gold Medal for Botany and a D.Sc. In the First World War he enlisted in the Royal Engineers but was recalled while on the way to France in order to become superintendent of the Detonator Department of Nobel's Explosive Co. In 1919 he joined the Geological Survey in Nigeria and returned in 1921, as a plant physiologist, to the Imperial College of Science and Technology, where eventually he became professor of timber technology. He investigated the relationship of the food reserves of hardwoods to *Lyctus* powder-post beetle attack, and his book *Timber, Its Properties, Pests and Preservation* is still widely used. He was an outstanding lecturer and was extremely popular with his students.

During this period, Henderson also became director of biological studies at the Sir John Cass Institute (1932–39) and superintendent of examinations in biology for the Pharmaceutical Society from 1928 until 1945. With T. A. Oxley, now director of the Forest Products Research Laboratory, but then at the Pest Infestation Laboratory, Henderson investigated the physiology of grain storage.

In 1945, Prof. Henderson was appointed director of the Forest Products Research Laboratory when post-war timber shortages were a severely limiting factor in the reconstruction of Britain's economy. Investigations into the properties of tropical timbers helped to introduce many new species to the trade.

The programme of the Laboratory was concentrated on the utilization of home-grown timbers when the afforestation schemes, begun after the First World War, yielded mature timber. Henderson co-ordinated programmes of work by serving on the research committees of the Timber Development Association and Furniture Development Council. An excellent chairman of committees, he formed panels with industrial representation to plan work on adhesives and plywood which later became the Composite Wood Panel.

An exceptionally modest man with a dry Scots humour, Henderson was keenly interested in his staff and ever ready to help them in personal problems. His high sense of public duty was evidenced by his war-time service in the Home Guard, in which he commanded a platoon. He was a skilled craftsman in woodwork, a lover of music and a keen gardener. He married Elizabeth Douglas Pringle in 1932 and is survived by her and two daughters.

J. D. BLETCHLY

FOSSIL HOMINID REMAINS FROM UBEIDIYA, ISRAEL

By PROF. PHILLIP V. TOBIAS
Department of Anatomy, University of the Witwatersrand, Johannesburg

PROMINENT among the faunal and cultural discoveries in the Central Jordan Valley[1–4] has been a small series of hominid fragments found at Ubeidiya near the Jordan outlet of Lake Tiberias. The fauna with which they were found has been recognized as Cromerian, while the cultural remains have been classified by Stekelis as

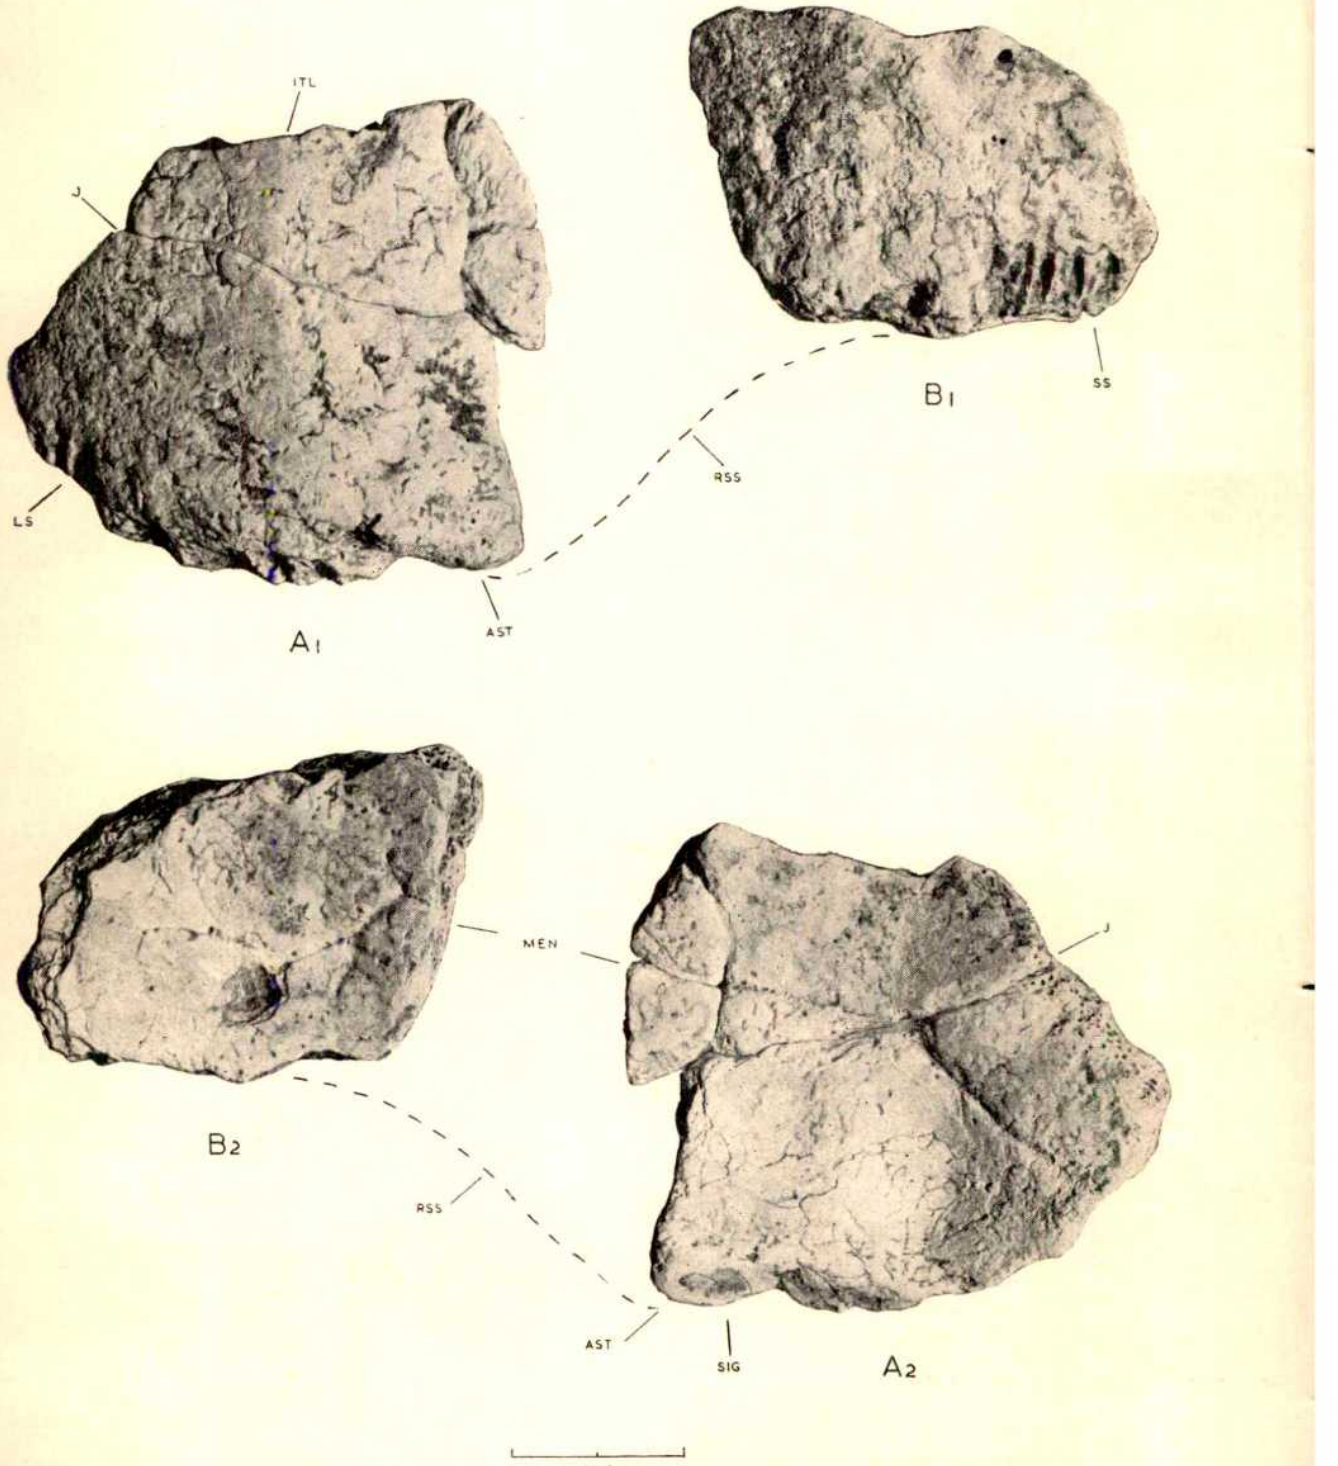

Fig. 1. Ubeidiya hominid right parietal fragment *A* (A_1, ectocranial; A_2, endocranial) and right parietal fragment *B* (B_1, ectocranial; B_2, endocranial). The two fragments are in approximately the correct alignment with each other, and the dotted line represents the probable position of the intervening portion of the squamosal suture. *AST*, Asterion; *ITL*, inferior temporal line; *J*, junction of *in situ* and bulldozed fragments; *LS*, lambdoid suture; *MEN*, meningeal vascular grooves; *RSS*, reconstructed squamosal suture; *SIG*, sigmoid sinus groove; *SS*, squamosal suture

Israeli Variant of Oldowan I and II, and Israeli Variant of Abbevillian.

Five pieces (two fragments of parietal bone, one of temporal bone, a molar and an incisor) can definitely be identified as of human origin, while a sixth morsel (possibly part of an occipital bone) is probably, though not definitely, hominid. Slight differences in the colour and texture of the fragments do not rule out the possibility that the pieces belonged to the same skull. Samples of all six remains were submitted to Dr. K. P. Oakley for relative dating.

Description of Remains

Hominid parietal fragment A (Fig. 1). The larger parietal fragment comprises four pieces, which fit well together and had been glued before I received them. Two of the fragments are very small and fit on to a third, bigger piece: this tripartite portion was exposed by a bulldozer. The fourth and largest portion, effecting perfect contact with the third, was later found *in situ* in layer 23 of the sequence. The hominid teeth were also found in this layer.

The combined fragment is from the asterionic region of a right parietal bone. On the endocranial surface is a sulcus occupied by branches of the middle meningeal vessels. Near the mastoid angle is a well-marked sigmoid sulcus, indicating that the sigmoid venous sinus rose on to the parietal bone. In *Homo erectus pekinensis* it does not extend so far upwards[5]. The ectocranial surface is marked by a robust inferior temporal line, which would be more in keeping with maleness than femaleness. Traces of the lambdoid suture are evident near the mastoid angle.

Towards the mastoid angle, an ectocranial heaping up of bone suggests a torus angularis, but the surface is eroded and damaged and the maximum development of the area would seem to be missing. Nevertheless, the heaping up at this point is sufficient to give the bone its large maximum thickness of 12 mm. Thicknesses elsewhere on this fragment vary from 7 to 11 mm.

Hominid parietal fragment B (Fig. 1). This smaller parietal fragment was uncovered by the same bulldozer. Two features help to place this fragment: an externally bevelled sutural surface, and a pattern of meningeal vascular grooves. The grooves are fine and shallow, in contrast with the broad, deeply etched grooves on fragment *A*. The general direction of the grooves is parallel to the sutural margin. The most likely area with these morphological features is the right parietal abutting on the squamosal suture in front of the midpoint between the mastoid and sphenoid angles, and therefore a short distance in front of parietal fragment *A*. Thus, fragments *A* and *B* could have belonged to the same parietal bone.

This fragment is also thick and its thickness varies from 9 to 11·5 mm.

The temporal fragment (Fig. 2*A*). This specimen comprises the lower part of the right squamous temporal, including a well-developed supramastoid crest, a distinct suprameatal spine and triangle, and the lateral part of the roof of the bony external acoustic meatus. A small portion of pars mastoidea is present and mastoid air-cells are exposed. A very small fragment of tympanic plate in the antero-superior part of the meatus abuts on to a process of bone, which is either a large postglenoid tubercle or perhaps the down-turned edge of the tegmen tympani: a squamotympanic fissure separates the process from the tympanic fragment. The structure is unmistakably human and the robust supramastoid crest suggests maleness rather than femaleness.

Indeterminate cranial fragment (Fig. 2*B*). This fragment cannot positively be identified as human. It may have belonged to the nuchal area of an occipital bone.

The molar tooth (Fig. 3). The entire crown and about 7 mm of the root of a right third upper molar was found *in situ* in layer 23. Unfortunately, much of the surface is eroded and morphological detail is partly obscured. In addition, the lingual half of the occlusal surface shows moderate attrition but no dentine is apparently exposed.

Despite the wear and erosion, the main cusps of the trigon are apparent. The worn mesiolingual cusp or protocone is ill-defined. Only a trace of the longitudinal occluso-mesial fissure is suggested, and this is so situated that the transverse (buccolingual) diameter of the protobone exceeds that of the paracone. No trace can be found of the occluso-lingual fissure. The moderate attrition is unlikely to have obliterated the lingual fissure if one had been present. It seems more likely that the fissure was poorly developed or absent: in other words, that the hypocone was nearly, or even entirely, absent, as is not uncommon in third molars. Poor development or absence of the hypocone occurs in some Neandertal teeth, such as those of Monsempron[6], Petit-Puymoyen, La Quina, and Krapina (the unworn third molar)[7]; in one or two of the seven third molars of Choukoutien[8]; and in modern man (see, for example, the Javanese material of Korenhof[9]).

The metacone is small but bulges buccally and distally. Its mesial limit cannot be located precisely. A mesiolingual prolongation of the metacone appears to make contact with the protocone, but no oblique or trigon crest connects the two cusps; instead, their line of contact is marked by a deep fissure running distad and lingualwards from the central fovea.

No posterior fovea is evident, but traces of the anterior fovea are present, connected by a slight mesial fissure to the central fovea. An anterior trigon crest connects protocone to paracone, mesial to the anterior fovea.

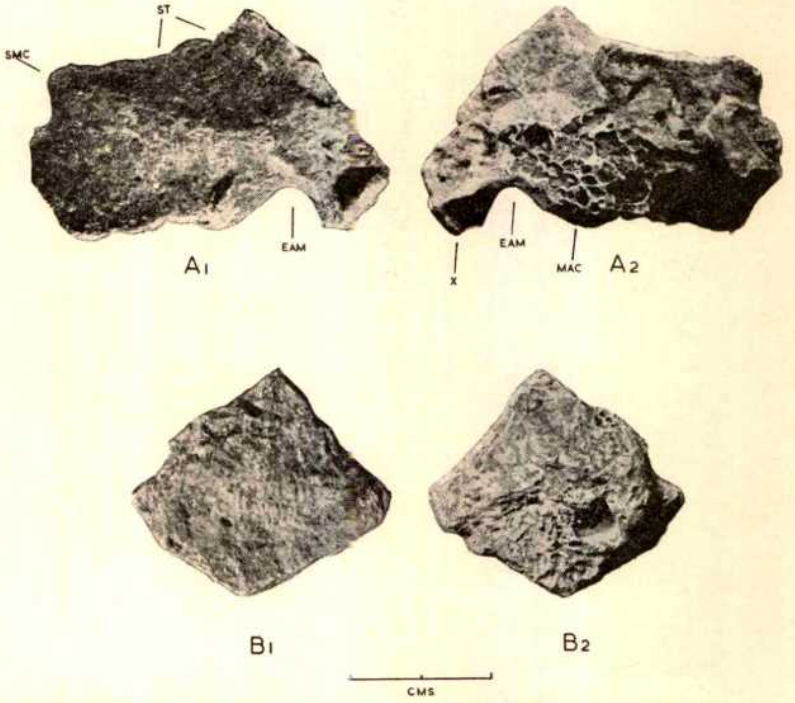

Fig. 2. Ubeidiya hominid right temporal fragment (A_1, ectocranial; A_2, endocranial) and possibly hominid cranial fragment, perhaps of occipital (B_1, ectocranial; B_2, endocranial). *EAM*, external acoustic meatus; *MAC*, mastoid air-cells; *SMC*, supramastoid crest; *ST* squamous part of temporal; *X*, down-turned process of bone

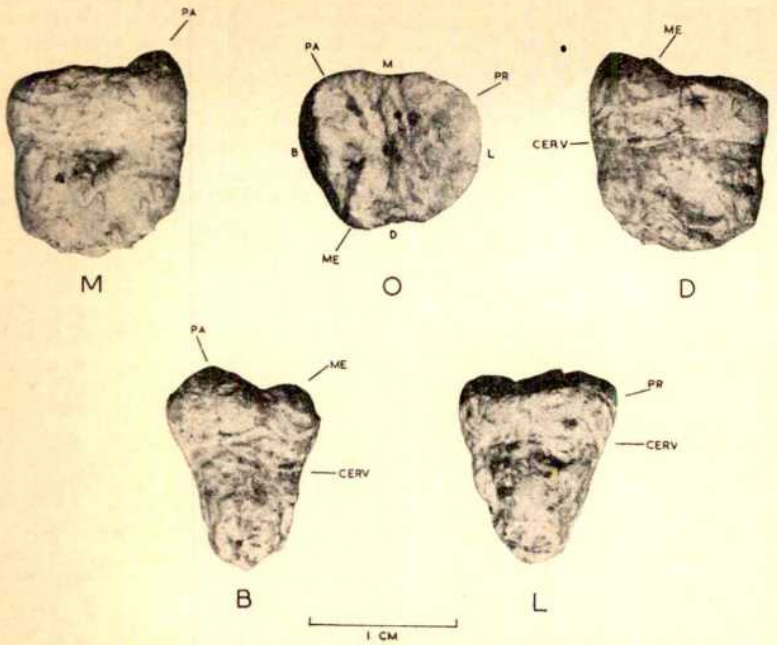

Fig. 3. Right third upper molar of Ubeidiya hominid. *M*, Mesial; *D*, distal; *B*, buccal; *L*, lingual (palatal); *O*, occlusal. *CERV*, Cervical enamel line; *ME*, metacone; *PA*, paracone; *PR*, protocone

The roots are fused so far as they are preserved, though separate root-canals are manifest. A longitudinal groove is apparent on the mesial face of the fused roots, between the larger buccal and smaller lingual components.

The diameters of the crown of the tooth are 9·6 mm (mesiodistal) by 11·4 mm (buccolingual). These measurements may be fractionally too small on account of the abraded surface. The metrical characters are compared with those for various other hominids in Table 1.

Table 1. METRICAL CHARACTERS OF MAXILLARY THIRD MOLARS OF UBEIDIYA AND OTHER HOMINIDS*

		Crown diameters Mesiodistal (mm)	Buccolingual (mm)	Module (mm)	Mesiodistal/ buccolingual shape index (per cent)
Ubeidiya		9·6	11·5	10·55	83·5
Homo erectus ($n = 10$)		8·7–10·8	10·4–14·0	9·55–12·4	77·1– 89·5
Australopithecus africanus ($n = 11$–12)		11·6–15·2	14·6–17·9	13·2 –16·5	77·7– 93·7
Australopithecus robustus ($n = 16$)		12·8–17·0	15·9–18·2	15·0 –17·4	70·3– 95·5
Neandertal man ($n = 13$)		9 –13	11 –14·5	10·0 –13·75	71·1–101·7
Modern man					
Aleuts	27♂	7·1–11·2	7·3–12·5	—	76·9–102·0
	15♀	7·8–10·2	10·2–11·0	—	70·9– 91·7
Bantu	265♂	6·3–11·0	9·1–14·3	—	61·5–104·7
	81♀	4·4–10·3	4·7–12·7	—	64·3– 93·6

* The figures for *H. erectus* and the australopithecines are from Tobias (ref. 10), Neandertal man after Patté (ref. 7) and Stewart (ref. 17), the Aleuts from Moorrees (ref. 11), and the Bantu from Jacobson (ref. 12).

The dimensions of the Ubeidiya third molar fall well below those of the australopithecines, but comfortably within the ranges for *H. erectus*, *H. sapiens neanderthalensis* and *H. sapiens sapiens*. The same might be said for its morphology: it is undoubtedly a hominine tooth, but nothing in its dimensions or morphology indicates to which species of *Homo* its owner belonged.

The incisor tooth (Fig. 4). A second tooth was found *in situ* in layer 23 and has been identified as a probable left lateral mandibular incisor. It is represented by the crown and the upper few millimetres of the root. The tooth is fairly well preserved, and even the perikymata are clearly detectable. The incisal edge is moderately worn and two small linear areas of exposed dentine are present; the mesial corner of this edge is right-angled, the distal corner rounded, exactly as described by Weidenreich for Pekin man[8]. The labial face is moderately curved from above downwards and strongly curved mesiodistally. On the lingual face is a definite though slight lingual swelling. The cervical enamel line on the mesial face extends upwards as a smooth curve, whereas on the distal face it ends in a point, higher up than on the mesial surface. The crown is narrow mesiodistally and shows little tendency to broaden from cervical line to incisal edge, the distal face bulging slightly more than the mesial.

The crown diameters are 5·6 mm (mesiodistal) and 5·6 mm (labiolingual), giving a module of 5·6 mm, a crown area of 31·36 mm² and a crown shape index of 100 per cent. These dimensions fall below those of australopithecine second incisors. The mesiodistal diameter falls within the sample range for *H. erectus*, just below the sample range for Neandertal man, and within the range for modern man, as judged by Aleut, Bantu and other series. The labiolingual diameter of 5·6 mm falls below the lower limits of all available fossil hominine incisors and can be accommodated only in the range for modern man. Even if we compare the labiolingual diameter of the Ubeidiya incisor with those of first incisors, its value remains well below the lower limits for available samples of *H. erectus* and Neandertal man. The differences are, however, not significant. In sum, the Ubeidiya incisor is very small and it can be accommodated somewhat more comfortably within series of modern human incisors than in samples of fossil hominine incisors. Notwithstanding, these comparisons cannot rule out the possibility that the owner of the tooth belonged to an extinct species or sub-species of *Homo*.

All the morphological features indicate hominine rather than australopithecine status for the individual(s) represented by this group of remains. The only decidedly archaic feature seems to be the great thickness of the parietal bone. The Ubeidiya thickness measurements are compared with other hominid data in Table 2.

The Ubeidiya parietal is thick, in comparison not only with the thin-skulled australopithecines and modern man, but also with the thick-skulled Neandertal group. On the other hand, it does not attain the thickness of the very thick-skulled *Homo erectus* group. An occasional normal modern cranium might attain a thickness of 12·0 mm in the asterionic region, but if the Ubeidiya parietal represents a normal and fairly typical member of its population, and not an extreme variant, we should have to regard its massive thickness as a truly archaic feature.

Nevertheless, on the fragmentary evidence before us, the Ubeidiya hominid cannot specifically be identified.

Fig. 4. Left lower incisor of Ubeidiya hominid. *LA*, Labial; *LI*, lingual; *D*, distal

Table 2. MAXIMUM THICKNESS (in mm) OF PARIETAL BONE NEAR MASTOID ANGLE

Ubeidiya	12·0	This investigation
Neandertal group	4·0–9·0 (mean 7·25)	Weidenreich[5]
Swanscombe	7·0–9·0	Campbell[13]
Spy I	7·1 (mean)	Twiesselmann[14]
Spy II	6·5 (mean)	Twiesselmann[14]
Fontéchevade	8	Vallois[15]
La Ferrassie	4	Vallois[15]
La Chapelle-aux-Saints	5	Vallois[15]
Piltdown	11·0 (mean)	Twiesselmann[14]
H. erectus pekinensis	13·5–17·4 (mean 14·8)	Weidenreich[5]
H. erectus erectus	14·0	Weidenreich[5]
Zinjanthropus	6·5–7·0	Tobias[10]
S. African australopithecines ($n = 6$)	4·5–12·0* (mean 6·4)	Tobias[10]
Modern man		
Unspecified	4·5–5·2	Martin–Saller[16]
Australians ($n = 16$)	7·75 (mean)	Twiesselmann[14]
Europeans ($n = 200$)	2–7	Twiesselmann[14]

* In five australopithecine crania, the thickness ranges from 4·5 to 6·5 mm (mean 5·6 mm), but in the Kromdraai cranium the thickness appears to be 12·0 mm (ref. 10).

The evidence presented by Miss Molleson and Dr. Oakley[18] that the hominid fragments are younger than the Cromerian fauna does not resolve the taxonomic problem: the Ubeidiya hominid could belong to an extinct or an extant taxon of *Homo*. It is hoped that the painstaking excavations of Profs. Stekelis and Haas will be rewarded by the discovery of further remains which it will be possible to identify. Meantime, the available evidence allows the assignment of the remains to the genus *Homo*, but does not permit recognition of the species. The present group of Ubeidiya hominid fossils should therefore be classified as *Homo* sp.

I thank Profs. G. Haas and M. Stekelis for their generous invitation to investigate these remains. I also thank Mr. A. R. Hughes for the photographs, and Miss J. Soussi for her assistance.

IMMUNOLOGICAL TOLERANCE OF THE FEMALE TO HOMOLOGOUS SEMINAL PLASMA PROTEIN

By JAMES O. MENZOIAN* and DR. MELVIN M. KETCHEL*
Worcester Foundation for Experimental Biology, Shrewsbury, Massachusetts

As a result of their sexual activity, women may repeatedly receive protein from another individual into their reproductive tracts. Although the females of most other mammalian species engage in coitus fewer times during their lives than do most humans, immunization of females against the components of semen, though rarely observed[1], might be expected to occur with repeated coitus. Seminal plasma proteins have served as antigens[2–4], and sensitization to foreign proteins has been shown to occur through the female reproductive tract[5].

The male ejaculate contains proteins in solution in the seminal plasma, and proteins which are part of the spermatozoa and other cells (mostly leucocytes) of the ejaculate. The leucocytes, though relatively small in number when compared with the spermatozoa, would be expected to be highly antigenic. Kiddy, Stone, Tyler and Casida[6] reported specific antibodies in the blood of heifers which received intrauterine injections of bull blood, though the sensitized animals were fertile when mated with the same bull from which the blood was taken. It has been demonstrated that antispermatozoal antibodies are formed if heterologous spermatozoa are injected[7–9] or introduced into the vagina[10,11]. Homologous spermatozoa have been shown to produce antispermatozoal antibodies and lowered fertility[12]. Franklin and Dukes[13,14] have recently reported the presence of antispermatozoal antibodies in the blood of some women. However, there does not appear to be any evidence that the spermatozoa, seminal fluid, or leucocytes entering the female reproductive tract during coitus have any detrimental effect on health or fertility.

Because ample evidence exists that the introduction of soluble antigens into the female reproductive tract results in specific antibody formation, we have undertaken a comparison of the antigenicity of homologous and heterologous seminal plasma proteins. Previous workers have found that the injection of heterologous seminal plasma proteins elicits specific antibody formation (see ref. 7). Because seminal plasma proteins do function as antigens, and because the female reproductive tract is a route by which immunization may occur, we formulated the working hypothesis that the female does not become sensitized to seminal plasma because she is immunologically tolerant to seminal plasma proteins of her own species. We reasoned that if the foregoing hypothesis were true, heterologous seminal plasma proteins would be antigenic if introduced into the female reproductive tract, while homologous seminal plasma proteins would not be antigenic even when injected intravenously or subcutaneously.

Adult virgin female rabbits were administered the antigen twice weekly. We utilized 'Bovine Albumin Fraction V Powder' (Nutritional Biochemical Corporation) as a control antigen, and bull and rabbit seminal plasma. Bovine albumin was dissolved in 0·85 per cent sodium chloride to attain a concentration of 200 mg/ml. Bull semen was obtained from a local supplier on the morning it was ejaculated, and rabbit semen was collected in our laboratory by means of an artificial vagina. The bull and rabbit semen were diluted three times with phosphate buffered saline and centrifuged three times at about 1,600*g* for 5 min to remove the spermatozoa. The diluted seminal plasma was kept frozen in small portions until used. Antigen was placed in the vagina of the test rabbit by means of a glass tube with a polished end which was inserted deep into the vagina. Great care was take to avoid trauma to the vaginal lining. No attempt was made to prevent leakage of the antigen from the vagina,

* Present address: Department of Physiology, Tufts University School of Medicine, Boston, Massachusetts.

though some leakage was observed with all three antigens used. Antigens were administered twice weekly. No attempt was made to keep the dose of antigen the same for each injection, but rather to build up an antibody response as quickly as possible by giving as much antigen at each injection as the rabbit seemed able to tolerate. Blood samples were drawn from each rabbit at intervals during the course of the experiment for testing.

Double-diffusion agar plates were prepared according to the method of Ouchterlony[15], using a 1 per cent solution of 'Special Noble Agar' (Difco). After antigen and antisera were placed in the appropriate wells, the plates were placed in a moist chamber at room temperature for 24 h and then observed for signs of precipitation. Heavy precipitation was given a rating of + + + +, and very light precipitation was given a rating of +; + + and + + + reactions were intermediates. Reactions were designated as negative only when no evidence of precipitation could be discerned.

The results of these experiments are summarized in Table 1. Rabbits which received a total of 800 mg of serum albumin intravenously or 950 mg of bovine serum albumin subcutaneously were observed to be + + + + shortly after the final injection. Intravaginal doses of 3,750–4,550 mg of the same preparation of antigen were required to obtain + or + + reactions. These results provide an approximate assessment of the relative antigenicity of the same antigen administered by way of the intravaginal route as compared with the intravenous and subcutaneous routes. In order to determine whether or not the antigen was being absorbed through the peritoneum, tubal ligations were performed on two of the rabbits 2 weeks preceding the initiation of antigen treatments. No difference in antibody titre was observed between rabbits with and without tubal ligations.

Table 1. A COMPARISON OF ANTIBODY RESPONSE TO BOVINE SERUM ALBUMIN, BOVINE SEMINAL PLASMA AND RABBIT SEMINAL PLASMA

Antigen	Route	Notal No. of injections	Total amount of antigen injected	Response
Bovine serum albumin	Intravenous	4	800·0 mg	+ + + +
	Subcutaneous	4	950·0	+ + + +
	Intravaginal	10	4,550·0	+
	Intravaginal	10	4,550·0	+
	Intravaginal*	8	3,750·0	+ +
	Intravaginal*	10	4,550·0	+
Bovine seminal plasma	Intravenous	3	2·5 ml.	+ + + +
	Intravenous	3	1·5	+
	Intravenous	3	1·5	+
	Intravenous	3	1·5	(anaphylactic death)
	Subcutaneous	6	9·0	+ + +
	Subcutaneous	5	5·0	+ + +
	Subcutaneous	5	5·0	+ + + +
	Subcutaneous	5	5·0	+ + +
	Intravaginal	9	15·0	+
	Intravaginal	9	15·0	+
	Intravaginal*	9	15·0	+
	Intravaginal*	9	15·0	+
Rabbit seminal plasma	Intravenous	12	21·0	– –
	Intravenous	6	20·0	– –
	Intravenous	6	20·0	– –
	Subcutaneous	12	21·0	– –
	Subcutaneous	6	20·0	– –
	Subcutaneous	6	20·0	– –
	Intravaginal	9	16·0	– –
	Intravaginal	9	16·0	– –
	Intravaginal*	9	16·0	– –
	Intravaginal*	9	16·0	– –

* Rabbits with tubal ligations.

Bovine seminal plasma injected intravenously caused a + + + + reaction after 2·5 ml. in one rabbit, and a + reaction after 1·5 ml. in two others. Another rabbit died of an anaphylactic reaction following the third injection. Subcutaneous injections of bovine seminal plasma resulted in + + + or + + + + reactions after 5–9 ml. of antigen. Four rabbits (two of which had tubal ligations) were observed to have a + reaction after receiving 15 ml. of bovine seminal plasma intravaginally.

Rabbit seminal plasma was ineffective as an antigen in rabbits. No discernible precipitates were seen in the blood after 16 ml. of antigen was placed intravaginally, nor after 21 ml. of antigen was injected intravenously or 20 ml. subcutaneously.

The finding that the female rabbit is apparently immunologically tolerant to the seminal plasma proteins of the male cannot be explained by the presence of blood plasma proteins in the seminal plasma, for some of the seminal plasma proteins are different from those that occur in the blood plasma[16]. One possible explanation for the immunological tolerance of the female to homologous seminal plasma proteins lies in the common embryonic origins of the male and female reproductive tracts and, more specifically, in the accessory sex glands of the female which are homologous to those of the male. The following consideration of accessory sex glands which occur in the female is quoted from Price and Williams-Ashman[17]. "In many female mammals, homologues of the male prostate and bulbo-urethral glands develop in the foetus. These glands may retrogress prenatally, remain vestigial, or develop postnatally and become functionally active. These homologues are the female prostate glands (paraurethral glands of Skene) and the bulbovestibular (major vestibular or Bartholin's glands). In addition, there are urethral glands (minor vestibular) which are homologous with the male urethral glands of Littre, and female preputial or clitordal glands corresponding to the male preputials. The major vestibular, when present, and the minor vestibular and clitordal glands are *functional* in many mature females. In a few cases, well-developed prostate glands which are actively secretory have been found in females of four mammalian orders."

We reasoned that the accessory sex glands of the female might be producing the same proteins as those in the seminal plasma of the male and, if this were so, might be present in the female reproductive tract. We therefore obtained five reproductive tracts from cows and five reproductive tracts from heifers. 150 ml. of saline was inserted into the fimbrium of a Fallopian tube and flushed out through the vagina. This was repeated with the same 150 ml. of saline for each Fallopian tube of each cow reproductive tract. The process was repeated with another 150 ml. of saline for the heifer reproductive tracts. A highly reactive rabbit antiserum obtained by injecting bull seminal plasma intravenously was then adsorbed against cow blood plasma until no further precipitate was obtained. The adsorbed rabbit anti-bull seminal plasma serum was then tested against the washings from the cow reproductive tract and from the heifer reproductive tract. In both cases, significant precipitates were formed.

The possibility existed that the rabbit antiserum against bull seminal plasma contained antibodies against bull protein that were not limited to the seminal plasma. If that were true, the washings which we obtained from the reproductive tracts of cows and heifers could have contained such proteins. Therefore, the rabbit antiserum against bull seminal plasma protein was adsorbed with cow blood, saline extract of homogenate of beef liver, and saline extract of homogenate of beef kidney. When adsorbed antiserum was then reacted with washings from cow and heifer reproductive tracts, a precipitate formed.

It therefore seems that the immunological tolerance of the cow to seminal plasma protein can be explained by the presence of the same protein in the female reproductive tract. Some of the proteins common to the cow and the bull reproductive tract are not found in blood, liver or kidney. The present evidence does not indicate the source of these proteins in the female. While it is evident that other possibilities exist, a reasonable expectation would be that the accessory sex glands of the female reproductive tract produce the same proteins as do their homologous glands in the male reproductive tract.

NUCLEIC ACID SYNTHETIC PATTERNS IN SYNCHRONIZED MAMMALIAN CELLS

By Dr. FREDERICK H. KASTEN and FREDY F. STRASSER

Pasadena Foundation for Medical Research, Pasadena, California, and Department of Anatomy, University of Southern California School of Medicine, Los Angeles, California

As a result of a number of elegant autoradiographic analyses of cytological systems, it is recognized that chromosomal DNA replication occurs in definite sequential patterns[1]. Not only is the sequence well ordered but the length of the synthetic (*S*) phase appears constant in relation to other phases of the cell cycle[2]. An excellent review of the cell cycle is given by Baserga[3]. Some insight into the operation of the genetic control mechanism responsible for this stability requires analyses of biosynthetic DNA patterns during the cell cycle. It is equally important to delimit the replication period with respect to time of other macromolecular components as well, so as to understand their modes of interaction with DNA. Randomly growing cell populations obviously present difficulties because of the exact nature of the DNA synthetic process. The use of synchronized cultures obviates this difficulty and allows precise autoradiographic analyses of synthetic patterns of nucleic acids and proteins. The present article is concerned with observations of the patterns of incorporation of tritiated thymidine into DNA and tritiated uridine into RNA.

CMP human epithelial adenocarcinoma cells were synchronized in tube cultures by double-blockage with excess thymidine, as described previously[4]. After removal into normal medium at the end of the second blockage, the cell population emerged as a synchronized unit into the *S* phase. Tritiated thymidine was added for a 1-h pulse at 12·5 μc./ml. (New England Nuclear Corporation, Lot 108–55–114, 6·7 c./mM) and then fixed in Carnoy's acetic–alcohol (1 : 3). At the beginning of the second hour of synchrony, another tube was labelled for 1 h. This pattern was followed for 14 h in all, a period long enough to include *S*, *G*2, *M*, and the onset of *G*1. Randomly growing cells were likewise exposed to labelled thymidine for 1 h. An identical sequential pulse procedure was followed using tritiated uridine at 20 μc./ml. (Schwarz, Lot 6501, 4·42 c./mM) to evaluate the incorporation patterns into RNA. Autoradiographic and staining procedures were carried out as described previously[4]. It was not possible to make quantitative grain counts because of the intense labelling at different times in the cell cycle, but the intracellular labelling patterns were evident.

There was no sign of DNA synthesis during the first hour of synchrony, as was shown by the complete lack of labelling with tritiated thymidine. This was undoubtedly due to the presence of an endogenous store of unlabelled thymidine from the previous blockage medium which was not yet fully metabolized. The typical pattern of RNA synthesis was also delayed in some cells during this first hour. For these reasons, the *S* phase was considered to begin at the end of the first hour in normal medium. All time periods mentioned in the subsequent discussion are corrected for the 1-day delay. Fig. 1 illustrates the dramatic increase in *S*-phase cells which took place in the first hour. By the third hour, almost 98 per cent of the population was labelled with tritiated thymidine. The fact that 95–98 per cent of the population exhibited DNA synthesis during a 3-h period (1–4 h), compared with 30 per cent in a randomly growing culture, demonstrates the remarkable degree of synchrony achieved in the *S* phase. The maximum percentage labelling at 3 h was followed by a gradual decrease to 10 per cent labelling after 11 h which remained constant during the next 2 h. This 10 per cent group represents the fraction of the population which was out of synchrony and was still synthesizing DNA when the main synchronized population was passing through during the *G*2 and *M* (mitotic) phases. The mitotic rate in this particular experiment attained a peak of 17 per cent at a single sampling time (11 h) following the initiation of DNA synthesis, a rate which was almost six times that measured in random cultures and sixty times higher than in blocked cells. In other synchrony experiments, we observed mitotic bursts as high as 50 per cent. Presynchrony treatment with 2·5 mM thymidine did not produce

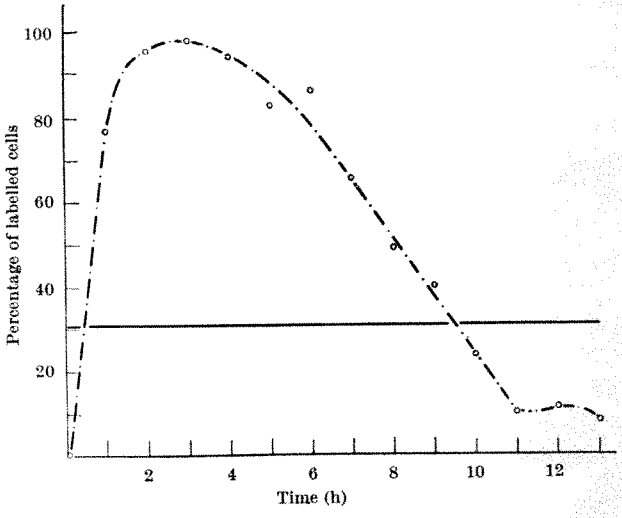

Fig. 1. Percentage of synchronized *CMP* tumour cells labelled with tritiated thymidine for 1 h in normal medium after final blockage in 2·5 mM unlabelled thymidine. Time 0 h occurs 1 h after blocked cells are placed in normal medium. A minimum of 1,000 cells were counted for each point indicated. A cell was considered to be labelled if its nucleus had any detectable silver grains over background. The unusually high level of synchrony is especially well demonstrated in the early- and mid-*S* phase (0–5 h) by the rapid and almost 100 per cent labelling rate. During the *G*2 (5–11 h) and *M* (11–12·5 h) phases, synchrony drops to 85–90 per cent. ———, Synchronized culture; ———, untreated control culture

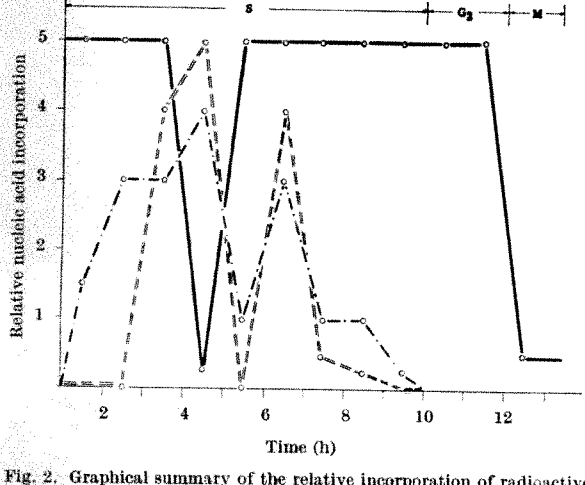
morphologically abnormal cells in the synchronized cycle which followed. Chromosomal anomalies due to the chemical mode of synchrony also were not observed at any time during the mitotic burst. Although we cannot entirely exclude the possibility at this time that the synchronized population was an abnormal one in terms of macromolecular synthetic patterns, this possibility seems highly unlikely in view of the actual cell cycle parameters we obtained. The breakdown of this particular synchronized population revealed an *S* phase of approximately 9 h, a *G*2 of 2 h, and an *M* phase of 1·5 h. Less than 1 h of the next *G*1 phase was sampled before the end of this experiment. The generation time of untreated *CMP* cells is about 28·5 h according to our unpublished ciné film analyses. Since 30 per cent of such a population is labelled after being pulsed with tritiated thymidine, the *S* phase is close to 8·6 h—a figure which corresponds well with the 9-h *S* phase observed in synchronized cultures. It was reported[5] that excess thymidine in a single treatment of 26 or 45 h produces an apparent stimulation of mitosis of cultured cells which results from a prolonged metaphase time. The conditions of treatment and results are entirely different from our experiments since we use two successive exposures to thymidine which produce an almost complete premitotic block.

The pattern of incorporation of tritiated thymidine showed unusual differences during the *S* phase. A graphical summary of the relative incorporation pattern based on visual analysis of all slides is presented in Fig. 2. Untreated control cells displayed a relatively uniform labelling pattern in nuclei undergoing DNA synthesis during exposure to tritiated thymidine. In some nuclei, there was also incorporation into nucleoli (Fig. 3). In early *S* (0–2 h), labelling was moderate and uniform over the entire nucleus, except for nucleoli which were almost devoid of synthetic activity, and became progressively more intense with time (Fig. 4). Beginning at 2 h, DNA synthesis was especially prominent in regions corresponding to nucleoli in size and appearance. Further support for intranucleolar DNA in *CMP* cells is based on cytochemical staining and ultrastructural evidence of chromatin[6]. Thymidine incorporation into nucleoli progressively increased and reached a high level 3–4 h in the *S* phase. During the same period of preferential nucleolar labelling, the remainder of the nucleus was still undergoing DNA synthesis, but at a lower rate than the nucleolus (Fig. 5). During the next hour (4–5) there was an abrupt stoppage of nucleolar DNA replication and a marked reduction of extranucleolar DNA synthesis. Thymidine incorporation picked up again between 5 and 6 h in both regions, leading



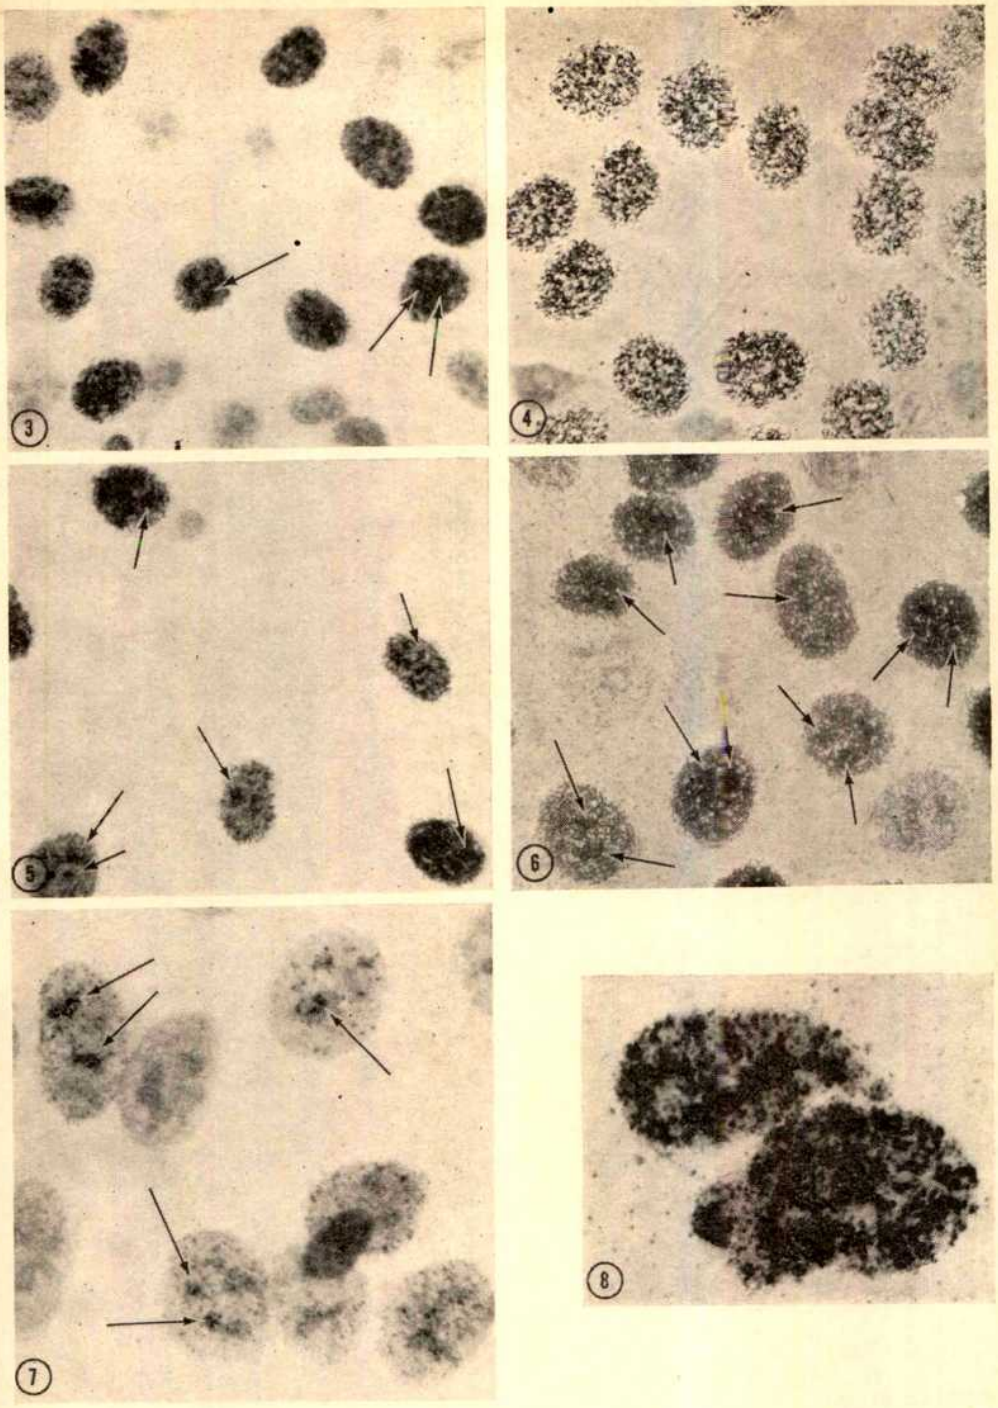


Fig. 2. Graphical summary of the relative incorporation of radioactive specific precursors into RNA and DNA of synchronized cells. Data are based on visual estimations of developed silver grains in autoradiographic preparations and are presented to illustrate dramatic changes in nucleic acid patterns. See text for discussion. ———, RNA; —·—·—·—, chromatin DNA; = = =, nucleolar DNA

to the synthesis of a second distinct nucleolar DNA fraction (Fig. 6). This fraction was still being synthesized between 6 and 7 h in some nucleoli (Fig. 7), but there was a general decline in nucleolar DNA synthesis. In the terminal end of the *S* phase, labelling was especially marked over heterochromatin, as judged by the concordance of grains with heteropyknotic blocks of chromatin (Fig. 8). The rate of DNA synthesis in nuclear chromatin was generally much greater in the mid-*S* phase (except for a sudden drop between 4–5 h) than in the early or late *S* replicating periods, as judged by the relative density of silver grains. The onset of the *S* phase was accompanied by a relatively high rate of incorporation of tritiated thymidine, whereas the termination of the *S* phase was attended by a slow decline in DNA synthesis. The small proportion of cells out of synchrony (10 per cent or less of the population) lagged behind the others and were detected during the mitotic burst and in the main *G*1 phase population (11–13 h). Some of the lagging group incorporated thymidine (*S* phase) or were fixed in cell division (*M* phase). Cells delayed in the *G*2 phase were unlabelled and contained larger nuclei than *G*1 phase cells.

With the exception of one brief period, there was a continuously high level of RNA turnover and probable net synthesis in nucleoli and chromatin of all cells throughout the DNA synthetic and the premitotic *G*2 phases (Fig. 2). The density of labelling over nucleoli, nuclei, and cytoplasm was in the approximate ratio of 6 : 3 : 1 respectively; the same was true for untreated control cells (Fig. 9). The exceptional pattern of RNA incorporation was first noticed at 2–3 h (Fig. 10) and became fully developed between hours 3 and 4 in the *S* phase. At this time, there was a complete absence of nucleolar RNA synthesis, a slight decrease in chromatin RNA synthesis, and a lack of cytoplasmic labelling of RNA (Fig. 11). Nucleoli were frequently outlined by grains in the perinucleolar regions, which suggested an incorporation into chromatin localized here. The sudden cessation of intranucleolar RNA synthesis coincided with the time of peak intranucleolar DNA synthesis. After the natural inhibition of nucleolar and extranucleolar RNA synthesis, there was an immediate return to the usual incorporation pattern (Fig. 12) which persisted into the *G*2 phase (Fig. 13). After exposure to tritiated uridine for 1 h, cells undergoing division frequently showed very low but clear-cut levels of radioactive RNA on the chromosomes and in the cytoplasm. The pattern of response was by no means uniform as many cells in mitosis showed no labelling at all, either on the chromosomes or in the extrachromosomal regions. These observations refer to cells labelled just before and during the mitotic burst (Fig. 13) as well as to randomly dividing populations (Fig. 9). We did not attempt to make a detailed analysis of the labelling pattern of different mitotic stages. Our results indicate that chromosomal synthesis of RNA during mitosis makes a negligible contribution to the total RNA produced during the cell cycle. Cells in the early *G*1 phase were small and demonstrated the typical RNA incorporation pattern described earlier for most of the *S* and *G*2 phases.

Nucleolar DNA has been reported in some cells on the basis of light microscopy of stained preparations[7]. Its presence is often regarded as exceptional and without significance since the nucleolus itself appears to be of chromosomal origin[8,9]. Following the work of McClintock[10] intranucleolar DNA was assumed by some workers to represent the attached nucleolar-organizing region of a chromosome which was genetically inactive and without special biochemical significance—a point of view which necessarily biases the interpretation of macromolecular control mechanisms[11]. A contrary and somewhat prophetic view was stated almost 20 years ago by Schultz[11]. Recent biochemical data[12], in addition to cytochemical[13] and electron microscope observations[14] of the nucleolus,

Figs. 3–8. Untreated or synchronized *CMP* cells exposed to tritiated thymidine at 12·5 μc./ml. for 1 h fixed in acetic–alcohol (1 : 3), and washed in 5 per cent trichloroacetic acid at 5° C for 15 min. Developed '*AR* 10' autoradiographs stained lightly with haematoxylin and eosin and photographed by bright-field except for Figs. 4 and 5. (Figs. 3–6, × *c.* 560; Figs. 7 and 8, × *c.* 965)

Fig. 3. Randomly growing control cells demonstrate intense tritiated thymidine incorporation into nuclear DNA. A few nucleoli also appear labelled (arrows) in addition to nucleolar-associated chromatin

Fig. 4. Synchronized cells in the very early *S* phase (1–2 h) demonstrate uniform DNA synthesis in the nucleoplasm. There is no apparent DNA synthesis in nucleoli. Phase-contrast photomicrograph

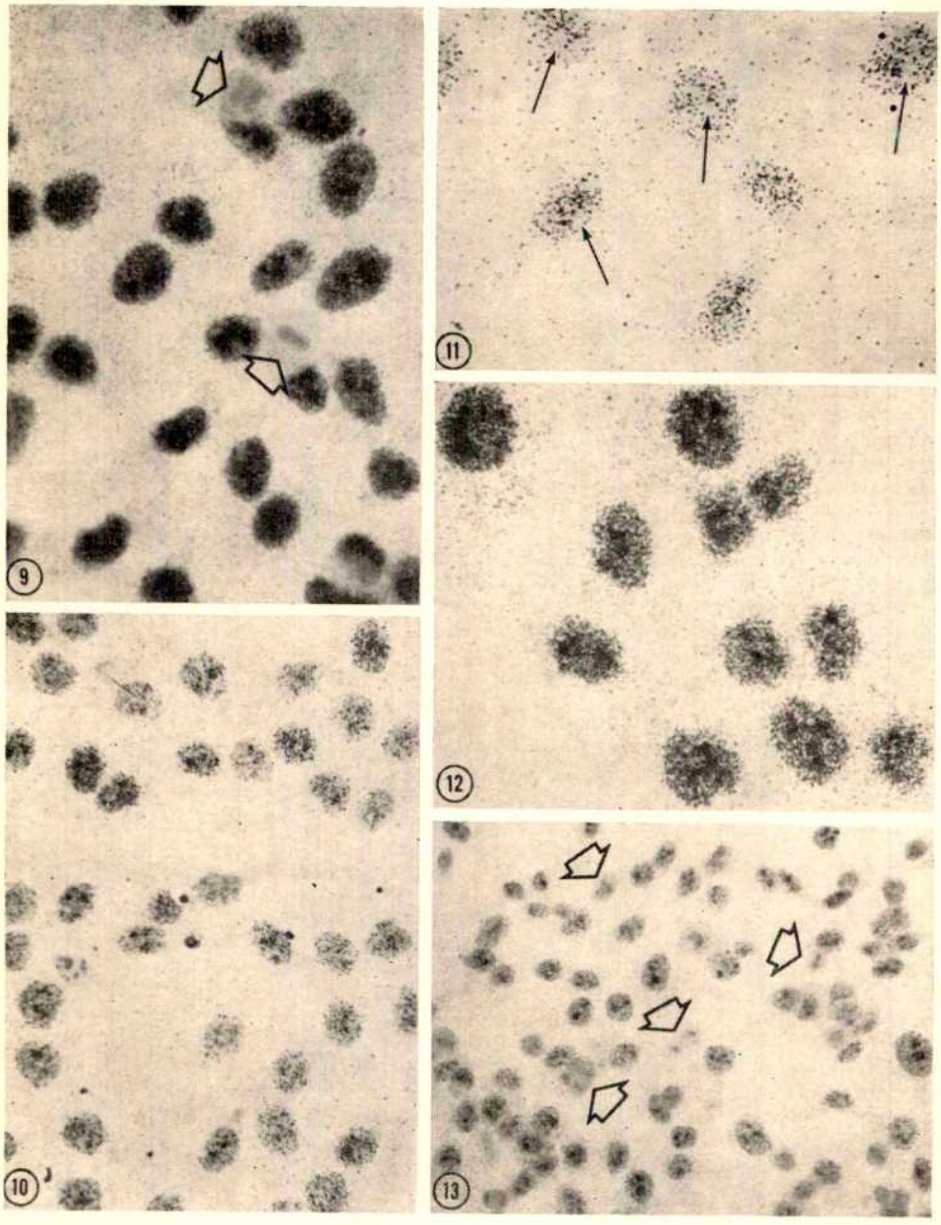

Fig. 5. During early *S* phase (3–4 h) the first intranucleolar DNA fraction is synthesized (arrows). Synthesis of this fraction is superimposed on extranucleolar DNA replication

Fig. 6. Preferential tritiated thymidine incorporation is demonstrated into a second intranucleolar DNA fraction (arrows) between 5–6 h of the *S* phase. Phase-contrast photomicrograph

Fig. 7. Specific and exclusive replication of the second intranucleolar DNA fraction and its associated chromatin is revealed in several nuclei of a culture labelled between 6–7 h of the *S* phase

Fig. 8. Synthesis of heterochromatin is indicated in these nuclei where prominent heteropyknotic blocks are heavily labelled in the late *S* phase (7–8 h)

revealed distinctive RNA and protein fractions to be present. One of the first biochemical reports of nucleolar DNA was made by Monty *et al.*[12]. Since then, actively synthesizing DNA has been demonstrated by autoradiography at the light[15] and electron microscopic[16] levels. Untreated *CMP* cells contain large quantities of nuclear DNA, substantial amounts of which are concentrated in the perinucleolar and intranucleolar regions[6]. At the fine structural level, we observed that perinucleolar chromatin often intrudes directly into the nucleolar mass. In other cases, distinct isolated patches of chromatin lie within partly vacuolated areas of the nucleolus. The appearance of intranucleolar chromatin stained with metallic salts is identical with that found in the perinucleolar region and the marginal nuclear areas. This morphological similarity may not extend to chemical base composition since it is known that a DNA template with a high adenine and thymine content gives rise to an RNA of high guanine and cytosine content in the region of nucleoli[17]. In cultured cells infected with DNA viruses such as *SV40*, substantial quantities of Feulgen-positive material are observed within the nucleolus in very early stages of infection[18]. At the ultrastructural level, unusual dense particles, which appear to be DNA viral cores, are

Figs. 9–13. Untreated or synchronized *CMP* cells exposed to tritiated uridine at 20 μc./ml. for 1 h. Subsequent handling is the same as described for preceding plate. Photomicrographs obtained by bright-field. (Figs. 9, 11 and 12, × *c.* 560; Figs. 10 and 13, × *c.* 220)

Fig. 9. Randomly growing control cells. Radioactive RNA is heaviest in nucleoli, followed by nucleoplasm and then cytoplasm. Cells in metaphase and anaphase (arrows) are unlabelled.

Fig. 10. During the very early *S* phase (2–3 h), nucleolar RNA synthesis begins to be turned off. Incorporation into chromosomal RNA also is diminished

Fig. 11. Complete repression of nucleolar RNA synthesis is demonstrated in these synchronized cells labelled between 3–4 h in the *S* phase. Arrows mark several unlabelled nucleolar areas

Fig. 12. The normal intracellular pattern of RNA synthesis is resumed immediately following the natural RNA repression illustrated in Fig. 11. The photomicrograph demonstrates cells labelled between 5–6 h of the *S* phase. The incorporation pattern is typical of most of the *S* phase and of untreated control cells

Fig. 13. A low-power autoradiograph of synchronized cells exposed to the radioactive RNA precursor during the *G2* phase. Unabated RNA synthesis is demonstrated with the usual intracellular distribution of label found in control cells. A few cells are already in mitosis and do not appear labelled (arrows)

likewise observed within nucleoli of *SV40*- (ref. 19) and adenovirus-infected cells[6]. It is reasonable to assume that the mechanism responsible for intranucleolar viral DNA synthesis also operates at a lower level of activity in uninfected cells.

As detected and defined in the present report by its first appearance in the early *S* phase (2·5–3·5 h) and again in a second burst of synthesis soon afterward (4·5–5·5 h), this intranucleolar DNA undergoes its own distinctive pattern of renewal as does the DNA found elsewhere in the nucleus. The extent to which either of these fractions is a part of the nucleolar organizing chromosome region is not known with certainty. However, we are inclined to regard the second one as genetically inactive or repressed (hoterochromatin) and to be derived from the nucleolar organizer since there are no significant RNA renewal changes in the nucleolus during its period of replication. It also is synthesized later in interphase when extranucleolar heterochromatin is duplicated. The first nucleolar DNA fraction may likewise represent part of the normal chromosomal complement, but in view of the concomitant RNA changes which accompany its replication we attach greater significance to it and regard it as a reservoir of genetic information and a possible site of the DNA control mechanism (see later discussion). Taken collectively, these observations and others on nucleolar function[20] would suggest that this organelle is more than a repository or transient stop for nucleoproteins but serves important synthesizing functions, one of which is the production of at least one biochemically significant DNA fraction.

There seems to be general acceptance of the concept, DNA⟶RNA⟶protein, in which DNA serves as a template for the formation of messenger RNA which, in turn, is essential for cytoplasmic protein synthesis in ribosomes[21]. With low doses of actinomycin *D*, it was shown that binding of the DNA template[22] prevents the action of DNA-dependent RNA polymerase[23] and selectively blocks nucleolar RNA synthesis[24]. Since RNA polymerase is a nucleolar constituent[25] and is normally associated with DNA[26], we emphasized recently[4] that nucleolar DNA is the logical site of the trigger for genetically coded RNA synthesis in the nucleolus. In this connexion, it was demonstrated by Granboulan and Granboulan[27], using electron autoradiography, that some nucleolar RNA is synthesized at the sites of nucleolar-associated chromatin. Blockage of DNA with 5-fluorodeoxyuridine prevents the formation of ribonucleoprotein in granular components of the nucleolus[28]. Our present results substantiate this relationship, as we detected a complete block in nucleolar RNA synthesis in the early *S* phase during the time when the first nucleolar DNA fraction was being replicated. The normal presence in the nucleus of messenger RNA[29] and transfer RNA[30] would suggest that these fractions are all responsive to nucleolar DNA. The fact that chromatin RNA production was also depressed at the same time as nucleolar RNA in our experiments suggests that this RNA fraction also is nucleolar DNA-dependent. The second nucleolar DNA fraction, which is synthesized as a block in the mid-*S* phase, apparently does not code for nucleolar RNA as does the first fraction since RNA synthesis continues unabated in this region.

Proceeding from this point, our working hypothesis is that in a multiplying cell population continuous renewal of DNA must occur, including template DNA of the nucleolus and chromatin. While template DNA is in the process of having both its strands replicated, primarily during the early *S* phase, it is impossible for either of these strands to serve as a matrix for RNA synthesis. As an obligatory consequence, RNA synthesis is temporarily switched off during this period. This may be considered as one of the periods of crisis during macromolecular replication in the cell cycle. In support of this hypothesis is a recent finding that a particularly sensitive DNA fraction is synthesized in the early *S* phase[31]. In addition, Prescott and Kimball's results on the ciliated protozoan *Euplotes* are in accord since they found that nuclear regions engaged in DNA synthesis were incapable of incorporating RNA precursors[32]. We should emphasize in this connexion that after this critical period of major template DNA renewal, when DNA replication occurs in various nuclear sites, continuous RNA synthesis is carried on in the chromatin and nucleolus. Presumably the synthesis of messenger RNA and coded ribosomal RNA precursors account for much of this main stream of RNA activity during interphase, which is in harmony with the suggestion of Hurwitz *et al.*[33] that the information for protein synthesis has to be continually renewed by the synthesis of new messengers. This stream of RNA is derived primarily from the nucleolus, which has already completed its template replication. However, the observation that there is continuous chromosomal RNA synthesis going on (except for the early crisis period) at the same time as DNA replication is under way suggests that additional multiple DNA template sites are continuously being inactivated and activated on the chromosomes, depending in part on whether or not they are undergoing replication. We are aware that part of the labelled RNA may not be DNA-dependent and may have undergone some translocation during the labelling period, but do not propose in this article to enter into the question of the origin(s) of cellular RNA[34]. Continuous RNA synthesis throughout interphase has been reported[35] and is generally confirmed in our investigations. The fact that this pattern is interrupted briefly in both chromatin and nucleoli of early *S* phase cells is a new finding to our knowledge, but is not unexpected in view of other evidence that RNA synthesis may be interrupted during the cell cycle[36].

On a molecular level, the model requires template DNA to be in the double-stranded state while coding the synthesis of RNA and in a partially unwound but replicating state at other times during the *S* phase. In this connexion, it is known that RNA polymerase is more active when primed by non-replicating DNA than by single-stranded DNA[37]. It may be premature to speculate further about the molecular nature of a DNA-protein model which allows multiple regions to prime the synthesis of RNA while other portions undergo self-replication. It has been suggested that chromosomal DNA exists in at least two different molecular associations, an early labelling and a late labelling variety[38]. Our observations support the idea that RNA polymerase can initiate RNA synthesis from the middle of the DNA chain and can copy selected regions of the molecule[26]. We have not dealt here with the role of histones in the regulation of RNA synthesis[39]. Another suggestion, derived from our data, is that RNA polymerase is likely to be found associated with a template DNA fraction in the chromatin as well as with a nucleolar DNA template as already reported[25]. As a consequence, it is predicted that DNA-coded RNAs will be produced in both these regions. The fact that actinomycin *D* in low doses affects the nucleolus and in higher doses acts on chromatin as well[24] is in harmony with this concept. Additional support comes from the finding that ribosomal RNA may be coded by chromosomal DNA[40], in addition to being associated with the nucleolus[24,41].

The specific location of the genetic control system, which triggers and regulates the intranuclear DNA replication pattern, is a matter of conjecture at present. Although we consider nucleolar DNA to be a reasonable candidate for this role, this is only a working hypothesis at the moment which is supported by the findings of Harris[42]. There is other experimental evidence, as detailed in the present article, for stating that RNA synthesis is primed for the most part by intranucleolar DNA and to a lesser extent by chromosomal DNA. These principal template DNA fractions are themselves replicated during the early *S* phase of the cell cycle. Shortly afterwards, in the

mid-*S* phase, a second nucleolar DNA fraction is synthesized which is probably derived from the nucleolar organizer. It differs from the first fraction in its time relations and in the fact that nucleolar RNA synthesis is not simultaneously repressed.

This work was supported in part by research grants from the U.S. Public Health Service and the Milheim Foundation for Cancer Research. We thank Mr. Jørgen S. Hansen and Mr. C. George Lefeber for photographic assistance and Miss Marian Turner for laboratory aid.

Note added in proof: Relevant studies on amino-acid incorporation patterns during the cell cycle of synchronized mammalian cells were presented by the senior author at a symposium on "The Nucleolus, its Structure and Function", at Montevideo, Uruguay, during December 5–10, 1965, and will appear in a forthcoming monograph of *J. Nat. Cancer Inst.*

SECONDARY CLUMPING EFFECT IN HUMAN CITRATED PLATELET-RICH PLASMA PRODUCED BY ADENOSINE DIPHOSPHATE AND ADRENALINE

By DR. D. C. MACMILLAN

Department of Cardiology, Royal Infirmary, Edinburgh

THE addition of thrombin to platelet-rich plasma (PRP) induces platelets to release rapidly adenine nucleotides and 5-hydroxytryptamine[1], and the platelets undergo 'viscous metamorphosis'. As only a small amount of protein is released at the same time, it is probable that a generalized increase in membrane permeability does not occur. These changes may depend on adenosine diphosphate (ADP), which is released from the platelets[2]. The release of ADP and 'viscous metamorphosis' are also produced by collagen[3,4]. This article reports a secondary clumping phenomenon of human platelets which occurs at an interval after the addition of ADP and results in changes of the same magnitude as those produced by the addition of collagen or thrombin. Its presence or absence affects the response of any particular PRP to ADP and also to adrenaline.

Human citrated venous blood (0·38 per cent sodium citrate) was withdrawn by a two-syringe technique and centrifuged at 160*g* for 10 min. All containers were either plastic or siliconized glass. PRP was removed and stored at 37° C. 1-ml. samples of PRP were examined by the nephelometric method of Born[5] and the transmission of light was recorded continuously: the details of this technique have been described previously[6]. ADP (Sigma Chemicals, Ltd.) in saline was added by micrometer syringe in 0·5 to 2 per cent dilution of PRP.

The morphology of samples of PRP fixed in 4 per cent formalin[7] taken before and after clumping has been examined by phase-contrast microscopy. Single platelets were examined in wet films. This allowed platelets to turn over and aided identification of their shape. Three categories have been recorded: thin discs of normal size[8], larger degenerating shapes, and smaller irregular ovals plus spheres. Detail of clumps could only be seen after they had been firmly squashed between a coverslip and a slide[9]. The compression separated the platelets in

the clumps and so the clumps have been classified according to the resistance of the platelets to separation. 'Loose adhesion' indicates that most of the platelets in a clump have been separated; 'moderate adhesion' that individual platelets cannot be seen at the centre of the clump but are still visible at the edges; 'marked adhesion' that single platelets have not been separated even at the edges of the clump. Some plasma contained more than one type of clump and some clumps had the features of two grades of adhesion in different portions. The specimens were classified on the dominant features. The grades of adhesion could still be identified when the degree of compression was varied.

Platelets have been counted by the method of Dacie[10]. In the post-ADP specimens platelet debris and granules were present and were not included in the counts. The term 'maximal clumping' has been applied to specimens in which most clumps showed marked adhesion, and in which there were few clumps of less than fifty platelets and there were less than 25,000 single whole platelets/mm^3.

Supernatants were prepared from clumped specimens of PRP which had been stirred for 2–3 min after the addition of ADP or adrenaline by cooling the specimens to 4° C and centrifuging for 5 min at 1,250g. The supernatant was stored in ice. It was warmed to 37° C immediately before the addition of 0·25 ml. by plastic Mantoux syringe to 1 ml. of PRP. Platelet-poor plasma (PPP) was prepared from the same blood specimen used in each experiment. ADP was added to aliquots of this PPP which were then added to the PRP used for testing the supernatants. A calibration curve was thus obtained. The ADP-like activity in a specimen is given by multiplying the activity in the 0·25 ml. of its supernatant by five.

It has been shown previously that the stirring of disk-shaped platelets causes a swirling effect in the plasma, resulting in variable light transmission which when recorded gives an oscillating tracing[6]. Following the addition of ADP, there is rapid conversion of disks to irregular ovals and spheres. This reduces the resistance of the platelets to stirring and so there is a loss of oscillations and, due to the more uniform distribution of the platelets in the PRP, an initial decrease in light transmission. Clumping of these changed platelets results in a subsequent increase in light transmission. This sequence of changes produces a 'hump' tracing[6].

Fig. 1 shows the changes in platelet shape and clumping produced by the addition of different clumping agents to stirred PRP. 0·25 ml. of PPP or saline produced an increase in light transmission due to the dilution of the PRP and did not alter the oscillations or cause clumping. Adrenaline caused a gradual loss of oscillations and a slow increase in light transmission. Many clumps of platelets which had retained their disk shape were present. 5-Hydroxytryptamine (5-HT) and ADP produced an immediate hump tracing. Only a small subsequent increase in light transmission occurred following the addition of 5-HT. Thrombin produced a hump tracing but after a delay of 3–10 sec. The delay decreased as the thrombin concentration was increased. The clumping activity of adrenaline was inhibited by phentolamine and partially by adenosine (see later), and of all other clumping agents by adenosine. In addition, the action of 5-HT was also inhibited by phentolamine and of thrombin by heparin. These results confirm the observations of Born[12] and O'Brien[11,13,14]. Thus, the nature of a clumping agent present in a supernatant can be detected from the change it produces in platelet shape plus the effect of inhibitors on this change. The concentration of the agent can be determined from the increase in light transmission produced. When more than one clumping agent is present in a supernatant, the initial changes in platelet shape are those of the agent with the most rapid action. Quantitative estimation of one clumping agent in a supernatant containing more than one must be made in test PRP to which inhibitors of the other agents have been added.

The dose-response curve of PRP to the addition of ADP was examined. The PRP was stirred for 30 sec and then the ADP was added. The changes in light transmission were followed for 10 min (for 2 min at the same chart speed and 8 min at a slower chart speed (Figs. 2 left, 3 left)). Then the platelet count, the frequency of different sizes of platelet clumps and the morphology of the larger clumps were noted (see Table 1).

The response of a PRP to increasing concentrations of ADP appears as an increase in light transmission (clumping phase) followed by a decrease in light transmission (reversal phase) (Fig. 2 left). A small reversal phase was still present after the addition of 10^{-5} M ADP but not after 10^{-4} M ADP. The samples removed after stirring for 10 min (Table 1) demonstrated that increasing concentrations of ADP caused a reduction in the number of single platelets and small platelet clumps and an increase in the number of larger platelet clumps. The degree of platelet adhesion also increased with increasing ADP concentrations and 10^{-4} M ADP produced 'maximal clumping'. The addition of supernatant from a similar PRP to test PRPs (Fig. 2 right) demonstrated a loss of ADP-like activity between the time of adding the ADP and of testing the supernatant.

Fig. 3 left shows the response of another PRP. The addition of 5 × 10^{-7} M ADP (0·5) led to clumping and reversal phases similar to those illustrated in Fig. 2)

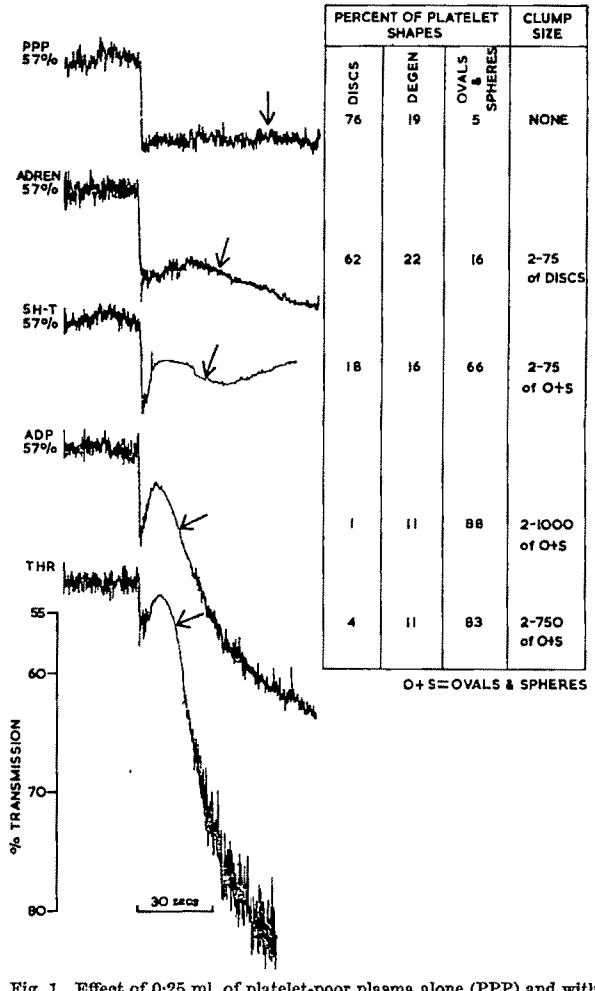

Fig. 1. Effect of 0·25 ml. of platelet-poor plasma alone (PPP) and with adrenaline (adren), 5-hydroxytryptamine (5-HT), and ADP and of 0·25 ml. saline with thrombin (THR) on platelet-rich plasma. The final concentrations were adren 4 × 10^{-6} M, 5-HT 5 × 10^{-6} M, ADP 2 × 10^{-6} M, Thr 0·2 u./ml. The percentages of single platelets which were disk-shaped, degenerating larger shapes (degen), and ovals plus spheres (O + S) have been averaged from six experiments

Table 1. EFFECT OF SECONDARY CLUMPING ON THE PLATELET COUNT, FREQUENCY OF DIFFERENT SIZES OF PLATELETS CLUMPS, AND MORPHOLOGY OF LARGER CLUMPS IN SPECIMENS OF PRP STIRRED FOR 10 MIN AFTER THE ADDITION OF ADP

	ADP initial concentration 1 unit = 1×10^{-6} M	Platelet count Th/mm³	Clumps 2–10 platelets	Clumps 10–50 platelets	Clumps 50–1,000 +	Morphology of clumps of 50–1,000 +
No secondary clumping (Fig 2)	PRP	385	+	+	–	–
	1·5	290	+ + +	+ + +	–	–
	4	167	+ + +	+ + +	+ +	*l*
	10	73	+ + +	+ + +	+ + +	*l* and *m*
	20	32	+ +	+ +	+ + +	*m* and *M*
	100	8	*r*	+	+ + +	*M*
Secondary clumping at 8×10^{-7} M ADP (Fig. 3)	PRP	360	+	+	–	–
	0·5	280	+ + +	+ +	–	–
	0·75	250	+ + +	+ +	–	–
	0·8	8	*r*	–	+ + +	*M*
	1·0	12	*r*	–	+ + +	*M*
	100	5	*r*	–	+ + +	*M*

The dose-response curves of the PRPs are shown in Figs. 2 and 3. 1 unit ADP = 10^{-6} M ADP, that is, 10 = 10^{-5} M ADP. + + +, Many; + +, several; +, few; *r*, rare; *l*, loose adhesion; *m*, moderate adhesion; *M*, marked adhesion.

The addition of 8×10^{-7} M ADP produced the expected clumping phase, but the reversal phase was interrupted by a second clumping phase which continued until the increase in light transmission equalled the change produced by 10^{-4} M ADP (100). There was no reversal of this secondary phase during the 10 min of observation. A specimen taken after stirring for 10 min showed that 'maximal clumping' had occurred. In this PRP an increase in the added ADP concentration of only 2×10^{-7} M caused fusion of the initial and second clumping phases. The addition of supernatant from a similar PRP to a test PRP demonstrated a marked release of clumping activity during the second phase (Fig. 3 right). This increase in clumping activity was inhibited by pre-incubation of the test PRP with adenosine. Heparin and phentolamine did not inhibit this activity. Thus it produced the same changes in this test system as ADP. This activity was only released by ADP when platelets were present in the plasma and the plasma was also stirred.

In some PRPs, therefore, a second clumping phase occurred which resulted in 'maximal clumping' and also the release of ADP. This phenomenon will be called 'secondary clumping'. It may occur at any ADP concentration from 10^{-7} M to 10^{-5} M. The change from the curve showing secondary clumping interrupting the reversal phase to the curve showing fusion of the two clumping phases was produced by a small increase in ADP concentration. These three phases cannot be shown on one tracing in most PRPs which require more than 4×10^{-6} M ADP to produce secondary clumping. It was possible to produce 'maximal clumping' in all PRPs (Fig. 2 in Table 1), but when secondary clumping had not occurred no increase in clumping activity could be demonstrated in the test system used (Fig. 2 right). Secondarily clumped specimens stirred for 1 h at 37° C showed some break-up of the smooth edge of the clumps. Increase in platelet debris gave a decrease in light transmission. There was no increase in recognizable single platelets.

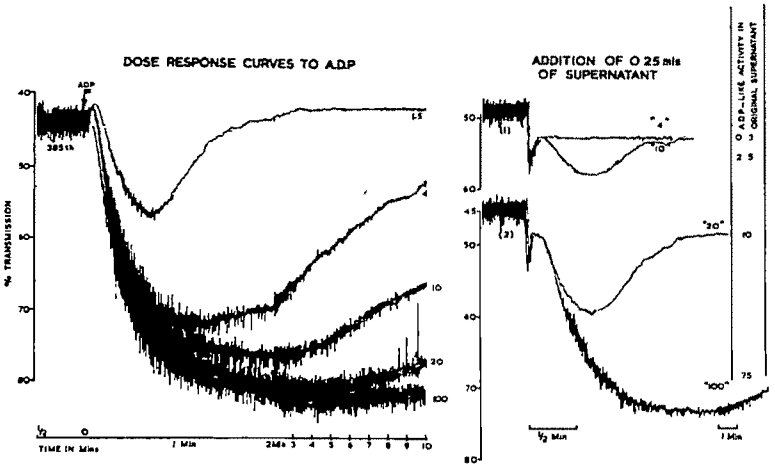

Fig 2. *Left*, Dose-response curve to ADP of PRP which did not give a secondary clumping phenomenon after the addition of ADP. 1 unit = 1×10^{-6} M ADP. *Right*, 0·25 ml. of supernatant from specimens of a similar PRP, stirred for only 2 min after the addition of ADP, has been added to two test plasmas (1) and (2) which had been previously calibrated with PPP containing known amounts of ADP. The parent specimen from which the supernatant was prepared is shown in quotation marks. The right column gives the ADP-like activity in the parent specimen

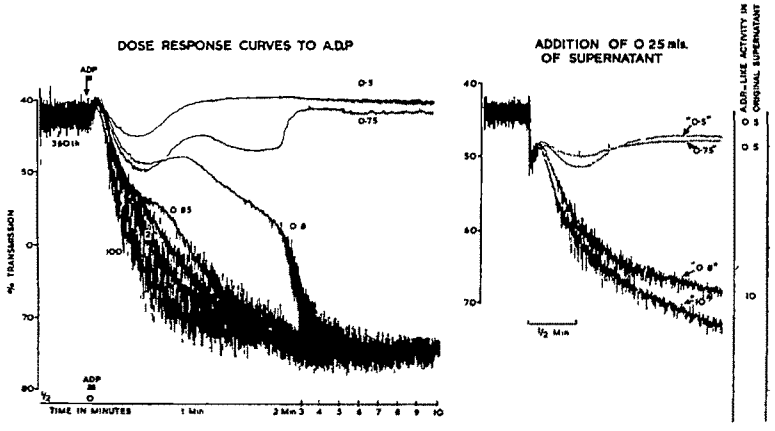

Fig. 3. *Left*, Dose-response curve to ADP of PRP which gave a secondary clumping phenomenon at 8×10^{-7} M ADP (0·8). 1 unit = 1×10^{-6} M ADP *Right*, 0·25 ml of supernatant from specimens of a similar PRP, stirred for only 2–3 min after the addition of ADP, has been added to PRP which showed secondary clumping at $1{\cdot}5 \times 10^{-6}$ M ADP

Secondary clumping resulted in the release of up to 10^{-5} M ADP-like activity (Fig. 3). One-eighth of the supernatant of a specimen which had been secondarily clumped by $7{\cdot}5 \times 10^{-7}$ M ADP contained sufficient activity to clump secondarily another specimen of the same PRP. Thus a self-propagating platelet clumping reaction can be produced *in vitro* despite dilution of the clumping activity released by the platelets.

Adrenaline induces one phase of clumping in all PRPs and two phases of clumping in most platelet-rich plasmas[15]. Secondary clumping to ADP and a second phase of adrenaline-induced clumping either were both present or were both absent in the same specimen of PRP when it was tested separately with both substances (Table 2). The concentration of adrenaline required to produce a second phase of clumping was in most instances less than the concentration of ADP required to produce secondary clumping (Table 2).

Adrenaline was added to PRP which was incapable of secondary clumping following the addition of ADP (Fig. 4). The initial changes shown in Fig. 1 occurred and many clumps of up to 1,000 disk-shaped platelets were present. Their formation was also associated with a variable loss of oscillations of the tracing. Phentolamine added after the formation of the clumps of disks rapidly reversed the increase in light transmission and oscillations reappeared. Microscopy showed only very few clumps of more than ten platelets.

In those PRPs which showed secondary clumping to ADP, a second phase of adrenaline clumping interrupted the first phase at a time after the addition of adrenaline which was directly proportional to both the adrenaline concentration and the ADP concentration necessary to induce secondary clumping. The second phase started with a reduction in oscillations which was associated with the presence of many oval and spherical platelets. This was followed by a rapid fall of the tracing and then the appearance of marked oscillations (Fig. 5*A*, *a*). At this point 'maximal clumping' was present. Equimolar phentolamine added during the first phase again caused complete reversal, but during the early part of the second phase reversal was only partial. No oscillations reappeared and some further clumping occurred after the addition of the phentolamine (Fig. 5*A*, *b*). The clumping at this point was not due, therefore, to adrenaline. However, the adrenaline stimulus was still required at this point for the second phase to proceed to maximal clumping. Phentolamine added later in the second phase did not influence the development of maximal clumping.

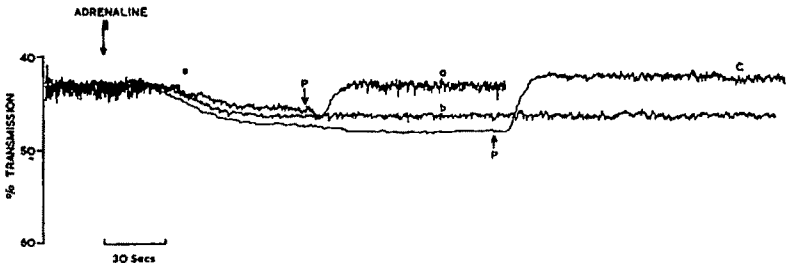

Fig. 4 Reversal of the first phase of adrenaline clumping by phentolamine. Phentolamine 2×10^{-5} M was added at the point *P* to PRP (*a* and *c*) after it had been clumped by adrenaline 2×10^{-6} M (*a* and *b*) and 1×10^{-4} M (*c*)

The supernatant from PRP maximally clumped by adrenaline (Fig. 5, *B*) produced an immediate hump curve in the test PRP. The test specimen containing phentolamine (which inhibits adrenaline and 5-HT) was clumped by the supernatant. This showed that ADP-like activity had been released during the maximal clumping and the fall in LT indicated that 'secondary clumping' had occurred. Both adenosine and phentolamine were required to inhibit completely the clumping activity in the supernatant. The clumping which occurred in the specimen which contained only adenosine (Fig. 5 *B*, *b*) was reversed by phentolamine. Thus adrenaline-induced clumping is not completely inhibited by equimolar adenosine.

In summary and conclusion, the addition of ADP or adrenaline induced one phase of clumping in all, and two phases of clumping in many, citrated plasmas when stirred maximally. The first phase was the direct result of the addition of the clumping agent. The adrenaline-induced first phase consisted of clumping of disk-shaped platelets and was rapidly and completely reversed by phentolamine. This may be unique to the catecholamines. The second phases produced both by ADP and adrenaline are a property of the individual plasma and resulted in clumping which did not reverse itself *in vitro*, and in the release of ADP-like activity. In those plasmas in which 'secondary clumping' occurs at low ADP or adrenaline concentration, a self-propagating reaction was present *in vitro* despite dilution of the ADP-like activity released by the platelets. The relationship of these phenomena to haemostasis and thrombosis requires investigation.

I thank Dr. M. F. Oliver for his advice and help and for providing research facilities, and Mrs. N. S. Davidson for technical assistance. This work was under-

Table 2. Relationship in Representative Specimens of Platelet-rich Plasma (PRP) between the Presence of Secondary Clumping to ADP and a Second Phase of Clumping to Adrenaline

Subject	PRP Platelets/mm³	Secondary clumping (ADP)	Second phase (Adrenaline)
AT	785	$2{\cdot}5 \times 10^{-7}$ M	5×10^{-9} M
KD	210	$7{\cdot}5 \times 10^{-7}$ M	5×10^{-8} M
BM	410	$7{\cdot}5 \times 10^{-7}$ M	2×10^{-7} M
JT	455	$1{\cdot}5 \times 10^{-6}$ M	1×10^{-6} M
CC	305	3×10^{-6} M	5×10^{-7} M
TH	307	4×10^{-6} M	$7{\cdot}5 \times 10^{-6}$ M
AA	360	5×10^{-6} M	5×10^{-6} M
JH	309	8×10^{-6} M	3×10^{-6} M
RWD	530	Absent	Absent
MH	260	Absent	Absent
NM	480	Absent	Absent

The lowest concentration producing secondary clumping has been recorded. Following the addition of ADP the PRP was stirred for 3 min and following adrenaline for 5 min.

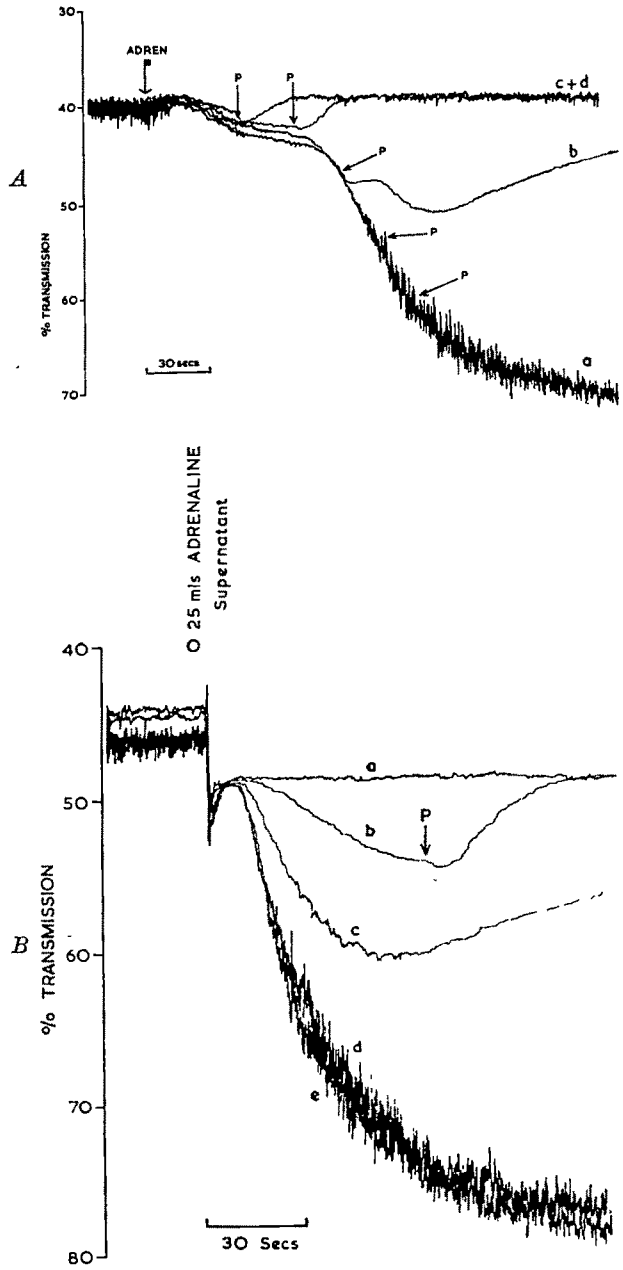

Fig. 5. *A*, The effect on the two phases of adrenaline-induced clumping (2×10^{-6} M) of phentolamine 2×10^{-5} M (*P*) added at increasing intervals after the addition of the adrenaline. During the first phase (*c* and *d*) complete reversal occurred; during the early part of the second phase (*b*) partial reversal occurred, and later in the second phase there was no reversal (*a*). *B*, The effect of inhibitors on the clumping activity present in the supernatant (0·25 ml.) from PRP maximally clumped by adrenaline. The initial increase in transmission is a dilution effect. The inhibitors present were: (*a*) incubation in advance for 5 min with adenosine 5×10^{-3} M and phentolamine 2×10^{-5} M; (*b*) adenosine only—phentolamine was added at *P*; (*c*) phentolamine only; (*d*) heparin, 25 u./ml.; (*e*) saline

THYROTROPHIN RELEASING FACTOR IN HYPOPHYSEAL PORTAL BLOOD

By DR. R. L. W. AVERILL*, D. F. SALAMAN and PROF. W. CURTIS WORTHINGTON, jun.†
Department of Human Anatomy, University of Oxford

SINCE the formulation of the hypothesis that the secretion of anterior pituitary hormones is controlled at least in part by neurohumoral agents passing to the pituitary by way of the hypophyseal portal vessels[1,2], evidence for the existence of a specific thyrotrophin releasing substance (TRF) has been forthcoming (for reviews see refs. 3 and 4). Proof that such releasing substances are concerned in regulation of pituitary activity requires their identification in the hypophyseal portal blood in concentrations which vary as appropriate pituitary activity varies[2,3]. We believed that rat portal blood, if it contained a substance(s) which could release rat thyroid stimulating hormone (TSH), might, when infused into the pituitaries of rabbits, increase the peripheral level of TSH in the recipient rabbits. The evidence presented in this article suggests the presence of a factor in the portal blood of rats which influences TSH release by the anterior pituitary.

Lister female rats of 160–200 g and males of 180–280 g from the colony of the Department of Human Anatomy, University of Oxford, were used. In the females, bipolar electrodes, and in the males, unipolar electrodes of platinum wire (s.w.g. 34) coated with glass except for 0·5 mm at the tips were placed stereotaxically in the anterior hypothalamus. These rats with implanted electrodes were screened (under urethane anaesthesia, 1,000 mg/kg, 10 per cent in 0·9 per cent saline) to determine whether electrical stimulation (50 c/s sine wave) for 30 min could elevate blood radioactivity levels while the rats were under a thyroxine (T4) dosage (5–10 μg T4/100 g/day) sufficient to prevent release from their thyroids of previously incorporated iodine-131. Of fifty rats screened in this way, sixteen responded with an increase in blood radioactivity, suggesting release of TSH as a result of stimulation. Stimulation was performed at voltages of 1·4–2·5 V and current readings ranging from 80–120 μamp (peak to peak).

7–10 days later, rats which had given a positive screening response were anaesthetized with urethane as before and prepared for the collection of portal blood from the severed pituitary stalk by a procedure described elsewhere[5]. After collection of an initial sample of 0·7–1·5 ml., stimulation was begun as before. Further portal blood samples were collected during stimulation. The volume of blood at several time intervals during collection was recorded, making possible an estimate of the overall rate of collection. The samples (in graduated tubes) were held in an ice bath, centrifuged, the haematocrit measured and the plasma stored at −10° C. The portal blood plasma was afterwards used for infusion into rabbits. Some samples were also assayed for TSH content.

Rabbit pituitaries were cannulated with platinum cannulae by the technique described by Campbell *et al.*[6]. 2–4 weeks later, rat portal samples of 0·135–0·160 ml. were infused at the rate of 0·065 ml./h into the conscious rabbits and peripheral blood samples of 2·5 ml. were withdrawn from the rabbit ear veins before and after infusion.

TSH was assayed in the rabbit peripheral blood samples and in four of the rat portal blood samples by an *in vitro* method described previously[7,8], and modified to allow expansion of the assay to include eight or nine unknowns. Rabbit TSH values were expressed as mU./100 ml. plasma. The values of λ obtained in these assays fell between 0·19 and 0·48, except in one assay (0·64) the results of which were discarded.

The electrodes of four of the sixteen screened rats became detached from the skulls before portal blood collection. Portal blood plasma was collected from the remaining twelve rats both before and during electrical stimulation. Assays of TSH in four of these samples showed that the levels before stimulation ranged from 68 to 208 mU./100 ml. while those collected during subsequent stimulation ranged from 5·3 to 39 mU./100 ml. plasma. These high levels are probably due to ischaemia of the pituitary after section of the portal vessels causing a passive leakage of TSH into the blood flowing backwards through the gland. Paired samples of stimulated and unstimulated plasma from the rat portal blood collections were infused into a total of fifteen rabbits through cannulae in the pituitaries. A 24–48 h period was allowed for recovery between the first and second infusions in those rabbits which received two. Half the rabbits were given the unstimulated plasma and half were given stimulated plasma at their first infusions. One rabbit died immediately after its infusion. The plasmas of two other rabbits were included in an assay of doubtful validity (λ = 0·64) and were discarded.

Nine portal plasma samples collected before electrical stimulation of eight rats were infused into the pituitaries of recipient rabbits. Peripheral TSH levels fell in five rabbits, but showed no significant change in the other four. The samples of portal blood collected from the same eight rats during electrical stimulation induced the following changes in the levels of TSH in the peripheral blood of recipient rabbits: in two the TSH levels rose, in two they fell, and in five they showed no significant change (see Table 1).

When the data from individual rats are compared across Table 1, it can be seen that while the pre-stimulation portal blood of rats Nos. 5, 13, 14, *M*9 and *N*6 caused falls in recipient TSH levels, plasma collected from the same rats during stimulation caused the level of TSH in the recipient to rise or to remain unaltered. In rat *M*7 (both plasmas from which induced TSH falls) and rat *M*9 the electrode tips were in the mamillary and premamillary areas respectively. In all other rats shown in Table 1, the electrodes were in the anterior hypothalamus. The exposed tips extended downward to lie above and in the ventromedial nuclei (Fig. 1). Sample 14 (ii) may indicate a decline in TRF activity after a short initial response to stimulation. For each rabbit in Table 1, the plasma TSH level after infusion is expressed as a

percentage of the same animal's initial level (*A* and *B*) taken immediately before infusion. The percentage responses for each paired infusion are combined to give an index of the net response by the rabbit pituitaries (*B*/*A*) to hypothalamic stimulation in the donor rat. The mean index of response for all paired portal samples was significantly greater than unity (2·57 ± 0·67, $P < 0.05$).

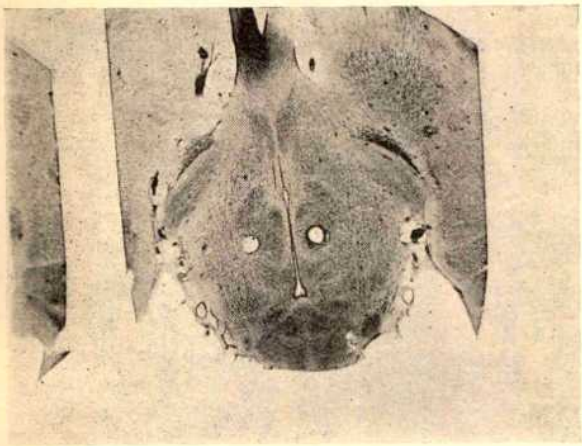

Fig. 1. Horizontal section through rat hypothalamus showing electrode tracks as holes in ventromedial nuclei. (× 17)

Although the onset of stimulation was always followed by an increased rate of flow of portal blood (mean before stimulation, 1·35 ml./h; mean during stimulation, 2·22 ml./h) the rate of flow was not correlated with the ability of the sample to raise or lower the blood TSH level in the infused rabbit. Thus flow in rat No. 5 before stimulation was at 1·2 ml./h and during stimulation was only 1·4 ml./h.

Plasma from blood samples obtained during the surgical approach to the pituitary stalk but before the stalk was cut, and plasma from the pituitary stalk of rats without electrodes, were infused into rabbit pituitaries as a control procedure. These samples did not raise the peripheral TSH levels in the recipient rabbits. In two out of four cases, a significant fall in TSH levels was induced, comparable to those shown in Table 1 after infusion of plasma collected before stimulation.

This series of experiments demonstrates that blood collected from the hypophyseal portal vessels after stalk section in the rat, when infused into the pituitaries of recipient rabbits, was able either to raise or to lower peripheral TSH levels, the direction of the change depending on whether or not the hypothalamus was stimulated electrically. It has been shown that under stressful conditions of surgery and anaesthesia there is a marked inhibition of TSH secretion in the rat[9,10]. Under the equally or more stressful procedures required for portal blood collection from the rat, the portal blood appeared to contain substances which depressed TSH levels in the recipient rabbit. When electrical stimulation was applied in the hypothalamus, however, the rat portal blood appeared to contain substances which either prevented this fall in the TSH levels of the recipient rabbits or in some cases caused them to rise. This was not a result of the TSH content of the infused plasma samples, as these were assayed directly for TSH in four cases and in each case the TSH level of the pre-stimulation sample was higher than that of the sample collected under stimulation. In an infusion volume of approximately 0·16 ml. there would be less than 0·3 mU. TSH, insufficient to be detected after its infusion into a 2·5–3·5 kg rabbit.

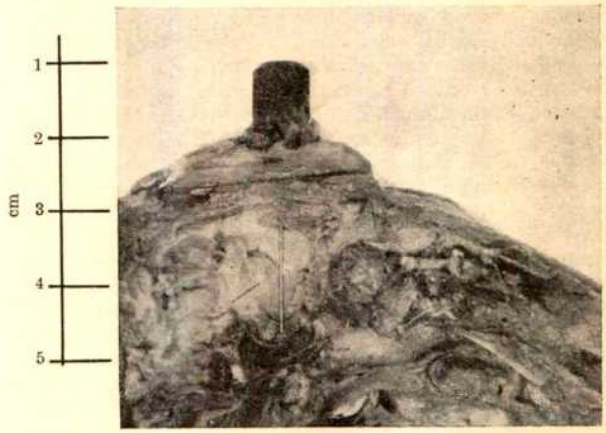

Fig. 2. Cutaway section of rabbit skull showing tip of cannula lying in the anterior pituitary. (× 3·1)

These preliminary findings, although by no means conclusive, are consistent with the hypothesis that following electrical stimulation in the hypothalamus TSH may be released from the pituitary due to the liberation of a thyrotrophin releasing factor (TRF) which passes by way of the hypophyseal portal vessels to the adenohypophysis. Further investigation into this problem is under way.

We thank Prof. G. W. Harris in whose laboratories this work was done, and Miss Linda Palfry for valuable technical assistance. The work was financed by a grant from the U.S. Air Force and by the U.S. National Institutes of Health and the Medical Research Council.

TOXICITY OF HEXAMETHYLPHOSPHORAMIDE IN RATS

By DR. RENATE KIMBROUGH and THOMAS B. GAINES
Toxicology Section, Communicable Disease Center, U.S. Department of Health, Education and Welfare, Atlanta, Georgia

CHANG *et al.*[1] reported that hexamethylphosphoramide (HMPA), an analogue of tepa, is an effective chemosterilant for houseflies. They emphasized that it has a low toxicity to mammals, and also that it has a wide margin of safety for flies between a lethal dose and a dose effectively sterilizing the males. Another advantage claimed for HMPA is that it is not an alkylating agent as, for example, are the ethyleneimine compounds which are also now being considered as chemosterilants. In view of the reported low acute toxicity of HMPA to mammals and its value as an insect chemosterilant, we undertook investigations of its toxicity to rats.

Male and female Sherman strain rats were used, and technical grade HMPA was either dissolved in water and given by stomach tube (while the controls were dosed with tap water) or mixed into ground Purina chow used as food. LD_{50} values for HMPA were determined according to the procedure developed by Gaines[2] for other pesticides; calculations were made according to the method of Litchfield and Wilcoxon[3]. All rats had free access to Purina chow and water. For white blood cell counts, blood was obtained by tail clipping. Complete autopsies were undertaken with most animals. Tissue for microscopic study was fixed in 10 per cent neutral formalin, and routine staining procedures were performed with haematoxylin and eosin. The left testis and epididymis were removed from a number of experimental male rats, which had been repeatedly dosed, and from a corresponding group of controls. This procedure was carried out with the animals under sodium pentobarbital anaesthesia 38–45 days after onset of exposure; microscopical examinations were then performed. These animals were then allowed to live for an additional 52 days.

The LD_{50} values for HMPA given by oral and dermal routes to adult rats are shown in Table 1. The compound when given by the oral route was more toxic to male rats than to females. The acute toxicity of HMPA by the oral route in male rats was less than that of the alkylating agents, apholate, metepa and tepa, by a factor of about 19 or greater. Gaines and Kimbrough[4] reported oral LD_{50} values of 98, 136 and 37 mg/kg, respectively, for the latter three compounds. Owing to considerable variation in the mortality among rats given single doses of HMPA by the dermal route, the LD_{50} could only be estimated. The main clinical symptoms observed in acutely poisoned rats were involuntary urination, mild muscle fasciculation, convulsions and bloody urine. (Large numbers of intact red blood cells were observed in the urine when it was investigated under the microscope.) Because HMPA is an organic phosphorus compound and because muscle fasciculation was observed, the blood cholinesterase level was determined titrimetrically in six adult male rats. When each animal was used as its own control, the change in plasma enzyme activity varied little (−3 to −42 per cent) at the time of most severe illness—about 3 h after an oral dosage of 2,000 mg/kg. Five hours after this dosage, there was some return to normal (+8 to −19 per cent). There was no significant change in red cell cholinesterase at any time.

Table 1. ACUTE TOXICITY OF HMPA IN ADULT SHERMAN STRAIN RATS

Route	Sex	LD_{50} (mg/kg)	19/20 conf. limits (mg/kg)	Lowest dose (mg/kg) Tested	Lethal
Oral	M	2,650	2,325–3,021	500	2,000
Oral	F	3,360	2,754–4,099	2,000	2,500
Dermal	M	3,500–4,500*	–	3,000	3,500
Dermal	F	3,500–4,500*	–	3,000	3,500

* Estimated.

A dose of 2,200 mg/kg was given to ten adult male rats. The total white blood cell and differential counts were determined before, 3 days after, and 1 week after treatment. The white blood cells did not appear to be affected. The only animals that showed a drop in total white blood cell count were 6- to 7-week-old male rats which had been treated daily with 400 mg/kg HMPA by stomach tube for 30 days. Their average count was 8,820 white blood cells/mm³ blood (range: 5,500–13,050); the total white blood cell count of ten controls of the same age averaged 16,670/mm³ blood (range: 10,600–23,050). The lowest single dose which resulted in a loss in weight in males was 1000 mg/kg; the lowest repeated dose with this effect was 100 mg/kg/day.

In order to determine acute tissue changes, six adult male rats that had been given a single dose of 2,500 mg/kg HMPA were killed when moribund (3 days after poisoning) and their tissues examined. Two instances of necrotizing cystitis and four instances in which the tubules of the kidneys contained red blood cells and hyaline casts were recorded; these findings are consistent with the haematuria mentioned earlier. Intra-alveolar haemorrhage and bronchiectasis were observed in three rats. The spleen was smaller than normal in all animals. Even among the six rats killed only three days after a lethal dose, the testes of two of them showed a reduced number of sperms and spermatids, and occasionally multinucleated cells were observed. As will be described later, the testis proved to be the organ most consistently affected by single or repeated doses of HMPA, but other organs were also affected in some animals. For example, repeated dosing produced bronchial pneumonia with the formation of abscesses in the poisoned animals. The pneumonia was not related to the stomach tubing (Table 2), as it also occurred in the animals which received HMPA in their diet but not in the animals which received only water by stomach tube. It is possible that HMPA affects the reticuloendothelial system and thus lowers the resistance to infection, as many poisoned animals showed very small atrophic spleens. The lymph nodes of these animals, on the other hand, were normal or enlarged.

In a further investigation of the effect of HMPA on the testes, additional groups of adult male rats were killed about 40 days after receiving single doses of varying amounts of HMPA by stomach tube. The lowest single dosage damaging the testes was 1,000 mg/kg; a single dosage of 500 mg/kg produced no effect. The lowest dosage given repeatedly by stomach tube to rats in which the testes were examined microscopically was 100 mg/kg/day, and this dosage caused testicular atrophy (see Table 2). When given in the diet at a level of 750 p.p.m., the daily intake, ranging from 80 to 40 mg/kg, produced partial or complete atrophy (Table 2). The testes were obviously smaller in living rats even when microscopic study revealed only partial atrophy. However, in a preliminary breeding experiment, it was found that when HMPA was administered by stomach tube at a rate of 25 mg/kg/day for 56 days it did not affect the fertility of male rats during that period, and the testes of the living animals appeared to be normal in size.

Microscopic examination of the testes, 36–41 days after a single dosage of 1,000 mg/kg or more, indicated that at

Table 2. PNEUMONIA AND TESTICULAR ATROPHY IN MALE SHERMAN STRAIN RATS CAUSED BY HMPA

Dosage level (mg/kg)	No. of doses Stomach tube	Diet	Days between last dose and pathological examination	Number of animals: Total examined	Killed	Died	With pneumonia	With partial or complete testicular atrophy
2,000	1		36–41	9	9	0	2	9
1,000	1		38	5	5	0	3	2
500	1		38	6	6	0	1	0
0	1		38	6	6	0	0	0

100	47		0	4	surgery*	0	–	4
	60–99		0	10	9	1	5	10
	48		0	4	surgery*	0	–	0
0	98		0	10	10	0	0	0
		45	0	5	surgery*	0	–	5
80–40†		61–103		11	8	3	8	11
0		45	0	3	surgery*	0	–	0
		103	0	8	8	0	0	0

* Left testis was removed under sodium pentobarbital anaesthesia. The same animals as well as others in the group that did not undergo surgery are included in the autopsy material.

† The dietary level of HMPA was 750 p.p.m. In the first few weeks the animals ate about 110 g/kg/day so that the intake of HMPA was about 80 mg/kg/day; later as the rats matured the average food intake dropped to 55 g/kg/day and the HMPA intake to about 40 mg/kg/day.

this time the spermatids are the cells of the seminiferous epithelium most affected by HMPA, but the effect is not uniform throughout the testes. Particularly after repeated dosing at or above the rate of 80–40 mg/kg/day, some tubules of some of the testes still contained normal or almost normal seminiferous epithelium while others were devoid of it or showed only a few atypical cells. We have called this condition 'partial atrophy', as in complete testicular atrophy (Table 2) all tubules showed loss of the seminiferous epithelium except for a few remaining spermatogonia. Similar pictures of partial or complete atrophy were also observed with metepa in an experiment conducted earlier[4].

A single dose of 2,500 mg/kg was given to six females. No effect on the female reproductive organs was observed when the animals were killed 36 days later.

HMPA was given to ten female rats by stomach tube at a rate of 200 mg/kg/day. The dosing began 7 days before mating to undosed males and continued until the twentieth day of pregnancy. The females were then killed and their uteri opened. The offsprings and placentae were weighed and examined grossly; the foetuses were fixed in Bouin's solution, and cross-sections were examined later under the dissecting microscope. Abnormalities were not detected in the offsprings of either the rats dosed with HMPA or eight female control rats that had been dosed daily for the same period with tap water. The weight of each foetus, the weight of each placenta, the number of animals per litter, and the number of resorption sites in the treated animals did not differ statistically from the controls.

A dosage of 100 mg/kg/day of HMPA is about 4 per cent of the acute oral LD_{50}. In earlier investigations in which metepa was administered by stomach tube, the lowest dosage level that caused partial testicular atrophy in some rats after 55 days was 10 mg/kg/day; this represents about 7 per cent of the acute oral LD_{50} dose. Metepa was found to be more toxic to rats when given daily by stomach tube in water than when given as a component in the diet—10 mg/kg/day by stomach tube had about the same effect as 76 mg/kg/day in the diet[4]. On the other hand, HMPA had about the same effect whether it was given in the diet or by stomach tube (see Table 2)—probably owing to its greater stability. Because of its stability, HMPA might present a greater problem as a residue than the ethyleneimines, which deteriorate rapidly, although both kinds of compound have a cumulative effect on the testes.

These data show that HMPA has a very specific effect on the testes of rats when fed at a dietary level of 750 p.p.m. which may be compared with a level of 2,500 p.p.m. in food necessary to cause 100 per cent sterility in male flies[1]. This comparison shows that the safety of any future use of HMPA must be based on its moderate toxicity to mammals and on limitation of their contact with it rather than on any important difference in the inherent susceptibility of mammals and insects to the compound.

CONVERSION OF PHENOTHIAZINE DERIVATIVES TO THE CORRESPONDING SULPHOXIDES ON THIN-LAYER PLATES

By J. KOFOED and DR. C. KORCZAK-FABIERKIEWICZ
Attorney General's Laboratory, Toronto, Ontario
AND
PROF. GEORGE H. W. LUCAS
Department of Pharmacology, University of Toronto

PREVIOUS experimental work[1] reported from this laboratory on the phenothiazine derivatives has dealt mainly with colour, crystal and spectrophotometric tests as a means of identification. In a preliminary report[2] at a meeting of the American Academy of Forensic Science, attention was directed to the value of the sulphoxides as a further means of identification of these drugs, and a method for preparing them quickly and accurately was described. The sulphoxides have been used only in a limited manner up to now, because only a few of them have been available commercially and their preparation in the laboratory was very tedious and time-consuming. The present article extends the data of the preliminary report and deals with a complete investigation of forty phenothiazine derivatives and their respective sulphoxides using ultra-violet spectrophotometry, thin-layer and gas chromatography. It also makes it possible now to investigate these phenothiazine derivatives and their sulphoxides using infra-red spectrophotometry.

Reference Compounds

A few sulphoxides were obtained from the various manufacturers. Others were prepared according to the

method of Schmalz and Burger[3]. 20 mg of the salt of the phenothiazine derivative were dissolved in 20 ml. of a solution prepared by mixing 20 ml. of 3 per cent hydrogen peroxide with 70 ml. of 85 per cent ethanol. The solution was heated in a water bath at 90° C for 3·5 h, after which time the *p*H was adjusted to 12 with ammonia. The sulphoxide formed was extracted with ether and the solvent evaporated. The identity of the finished product was established by means of its ultra-violet and infra-red spectra, colour tests, thin-layer and, where applicable, gas chromatography.

The ultra-violet spectrophotometric data were obtained on a Beckman '*DK-2A*' ratio recording spectrophotometer, the infra-red data on a Beckman '*IR-4*' infra-red spectrophotometer and the gas chromatographic work was done on a 'Microtek *GC-2500R*' gas chromatograph. A short-wave ultra-violet lamp, model '*SL2537*' (Ultra-violet Products, Inc., South Pasadena, California), was used to locate the spots on the thin-layer chromatography plates.

Each of the following drugs in the form of their salts was used in the experiments described here: chlorpromazine, thioridazine, trifluoperazine, thioproperazine, levopromazine, perphenazine, fluphenazine, triflupromazine, promazine and promethazine.

During routine work on the identification of phenothiazines it was observed that when a developed thin-layer plate was left in the open air for some days, the ultra-violet spectrum of an eluted spot no longer resembled that of the original product, but was close to that of its sulphoxide.

Gas–liquid and thin-layer chromatography confirmed that the sulphoxide had indeed been formed. Because of this certain conditions influencing the oxidation of phenothiazines on thin-layer plates were further investigated.

Plates were prepared for ten different compounds. Each plate contained eight spots of the drug assigned to it. The plates were developed in the solvent and were allowed to stand in open air in daylight at approximately 20° C. Each day one spot was eluted and the ultra-violet spectrum recorded. After an interval of 48–72 h, depending on the derivative under investigation, marked changes in the absorption spectrum had taken place; the spectrum began to resemble that of the corresponding sulphoxide. At the end of 8 days the spectrum was that of the pure sulphoxide (see Fig. 1). While a change in colour of the spot was noted a few minutes after the dry plate was exposed to the daylight, it was not accompanied by a change in the ultra-violet spectra. Gas–liquid and thin-layer chromatography confirmed that only the sulphoxide was formed.

Promethazine	249–299	234–260–295–330

The oxidation was complete at the end of 8 days and was dependent mainly on the availability of oxygen. When the ten compounds, spotted and developed on plates, were placed in total darkness in an oven at 20° C over circulating air for 8 days, oxidation was complete. If similar experiments were carried out without circulating air in darkness or in daylight no oxidation occurred. The same was observed when the plate, spotted in the usual manner, was kept in a tightly closed vessel in an atmosphere of nitrogen for 2 weeks. This was confirmed by gas–liquid and thin-layer chromatography.

These experiments emphasize the importance of having sufficient air (oxygen) in order to obtain conversion of the phenothiazines to their respective sulphoxides. It was also evident that light was not essential in the oxidation process.

Numerous adsorbent gels are available on the market for thin-layer chromatography. Our experience with 'Silica Gel *G*', 'Adsorbosil *P*-2', 'Aluminium Oxide *G*' and 'Chromsorb-*G*' is that they do not by themselves have any effect on the formation of the sulphoxides in these experiments. It was further established that the thickness of the gels was not a decisive factor in the oxidation reaction since the ultra-violet spectra obtained from phenothiazine derivatives on plates of varying gel thickness were identical under standard conditions. The gels were not affected by the presence of hydrogen peroxide used to oxidize the phenothiazine derivatives to their sulphoxides. After spotting with 10, 20 and 30 per cent solutions of hydrogen peroxide, plates with silica gel were chromatographed, dried, eluted and examined in ultra-violet light. No absorption was detected.

The oxidation reaction appears to be associated with a relatively large increase in the surface area of the phenothiazine drugs on the plate. Such increase is brought about by the development of the plate after spotting with the drug.

Effect of Ultra-violet Irradiation

No change in the ultra-violet spectra was observed on the spotted plate up to and after 4 days of irradiation with ultra-violet light in a dark room without circulating air. It was observed, however, that deep brownish colours had developed in the spots. A control plate placed in the same room but excluded from ultra-violet irradiation had acquired a faint brown colour only, but no change in the ultra-violet spectra was noted. It is our opinion that ultra-violet irradiation does not have any appreciable effect on the oxidation of the phenothiazines by the method used. Further experiments may shed some light on the changes occurring under these conditions.

Effect of Temperature

When a series of plates, spotted with these drugs, is placed in an oven at 60° C with circulating air, conversion to the sulphoxides becomes measurable after about 2 h and is complete after 3–4 days. A peculiar phenomenon was encountered when a plate spotted with phenothiazine derivatives and developed in the usual manner was placed in an oven with circulating air at 120° C. Contrary to our expectations, only traces of oxidized material were detectable by ultra-violet measurements at the end of 3 days. Further experiments are in

progress to elucidate this phenomenon. Oxidative activity was practically absent at low temperature; no oxidation took place on a plate left at 0° C for 5 weeks.

Formation of Colour

Our experiments were carried out on plates, some of which were exposed to daylight while others were kept in darkness or exposed to ultra-violet irradiation. Other plates, in addition, were maintained in ovens where air was not circulated, in jars where there was no circulation of air, or in an atmosphere of nitrogen. The temperature of the atmosphere in which the plates were kept was also varied. In each case a colour developed in the spotted areas and varied as described later.

When plates were spotted with these drugs and maintained in daylight at approximately 20° C with or without oxygen, colour developed in the spots within 15 min. In darkness, the development of colour was delayed. Under these conditions the colours varied widely, depending on the concentration of drugs used. Also, the colour of any individual spot was not uniform, but varied from light shades in the central areas to deeper and darker shades in the periphery, or vice versa. When ultra-violet irradiation was applied to spots at 20° C in a dark room without circulating air, colour developed about as rapidly as it did in daylight. The shades were pastel at first and resembled those on the plates exposed to daylight, but with longer irradiation they changed colour. In those developed in daylight, on the other hand, the shade of the colour increased. The temperature at which the plates were stored was important in the development of the colour. After 6 weeks at 0° C only faint spots were evident, whereas with temperatures well above 20° C the spots appeared very rapidly and were more intense.

Hydrogen Peroxide as Oxidizing Agent

In our preliminary report[2] it was shown that spots of phenothiazine developed on thin-layer plates could be oxidized rapidly to the sulphoxide, using 3 per cent solutions of hydrogen peroxide (see Fig. 1). At that time the optimum concentration of peroxide had not been determined. Further investigations have shown that the concentration of hydrogen peroxide is not critical, but that best results are obtained when the concentration is between 10 and 20 per cent. The oxidation product obtained in this manner on the plate was confined to one spot only, as can be seen in Fig. 1 above the spot treated with 10–20 per cent hydrogen peroxide. The R_F value corresponds to that of the pure sulphoxide. The optimum of hydrogen peroxide concentration was determined as follows.

In Fig. 2 the original compound chlorpromazine HCl was spotted in such a manner as to obtain a large spot without tailing and the chromatogram was allowed to develop in direction 1. The spot was outlined under ultra-violet light and one strength of peroxide was applied to the upper part and another concentration to the lower part of the spot. Two reference spots were applied on line with and next to the spot, one with chlorpromazine and one with chlorpromazine sulphoxide. The plate was

now allowed to develop in direction 2 perpendicular to the first one. This experiment indicated that in order to obtain a complete conversion to the sulphoxides for the quantity used, a concentration of at least 10–20 per cent hydrogen peroxide was essential. Below that concentration, only portions of the drug were oxidized and two spots were obtained on re-chromatographing. There was some indication that a second compound was formed when 30 per cent hydrogen peroxide was used together with hot air to dry the spot. This compound travelled behind the sulphoxide on the plate and might be the corresponding sulphone. The sulphoxides were identified by their ultra-violet spectra, colour tests, thin-layer chromatography and, where applicable, by gas–liquid chromatography.

Gas Chromatography

Gas chromatography is at present the most satisfactory method of separating and identifying the phenothiazines and their respective sulphoxides. Excellent separations were achieved using a 2-ft. 3 per cent '*SE*-30' column at different temperatures (Tables 3 and 4). It should be noted, however, that only very broad peaks could be obtained for the sulphoxides of the four phenothiazines with the highest molecular weights.

The retention times for these four compounds varied from 40 to 60 min. All compounds were injected in the free state as well as in salt form without any differences appearing in the chromatogram.

Proposed Method of Identifying Phenothiazine Derivatives

The phenothiazine derivative is spotted in the lower two corners of a thin-layer plate (20 cm × 20 cm) approximately 3 cm from the edges. The plate is placed in the developing tank, with the spots at the bottom, until the solvent has travelled to about 3–4 cm from the top, after which time it is taken out and allowed to dry. The spots are now outlined under the short-wave ultra-violet light (cited previously) and the right-hand one is just wetted with small drops of 10–20 per cent hydrogen peroxide solution added drop by drop. The spot is dried in a hot air stream (60° C), after which the plate is placed in the tank again with the peroxide-treated spot at the bottom and allowed to develop in a direction perpendicular to the initial one. In this way, two R_F values can be obtained, one for phenothiazine derivative and one for the sulphoxide. The spots can now be removed from the plate and eluted with distilled water. After the ultra-violet spectra are obtained from the supernatant, the original phenothiazine and its sulphoxide can be compared with reference compounds with the use of thin-layer and gas–liquid chromatography. It should be noted that even after the most careful elution the gel remaining in the centrifuge tube still contains some sulphoxide which can be demonstrated by colour tests.

Table 5 shows the ultra-violet spectrophotometric data on the forty phenothiazine sulphoxides investigated, together with the R_F values and those of the parent compound.

We thank Smith Kline and French Laboratories and Dr. I. S. Forrest, Biochemical Research Laboratory, *T*-47 Veterans Administration Hospital, Palo Alto, California, for supplying samples of sulphoxides.

MECHANISM OF THE CYTOTOXIC ACTION OF ALKYLATING AGENTS IN MAMMALIAN CELLS AND EVIDENCE FOR THE REMOVAL OF ALKYLATED GROUPS FROM DEOXYRIBONUCLEIC ACID

By DR. A. R. CRATHORN and DR. J. J. ROBERTS
Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, London

THE reaction of alkylating agents of the mustard type with cellular deoxyribonucleic acid has been proposed as the basis for their cytotoxic action[1,2]. In an earlier report[3] results were presented which supported this view in the case of the reaction of mustard gas di-(2-chloroethyl)sulphide with mouse lymphoma cells (Fisher *L*5178*Y*) growing in culture. In this work two cell lines differing by a factor of about 2·5 in their sensitivity to the agents were investigated. With the more sensitive line, it was found that a dose which killed 90 per cent of the cells resulted in a depression of about 50 per cent in the rate of DNA synthesis within the first 2 h. This was the only rapid biochemical effect which was observed, protein and ribonucleic acid synthesis not being affected. It was also observed, however, that administration of a similar dose of sulphur-35-labelled mustard gas to the resistant line, which had very little biological effect, resulted in a similar extent of reaction of alkylating agent with the DNA of the cells. Walker has also recently reported[4] that the DNA of cells in the *S* or G_2 phases of

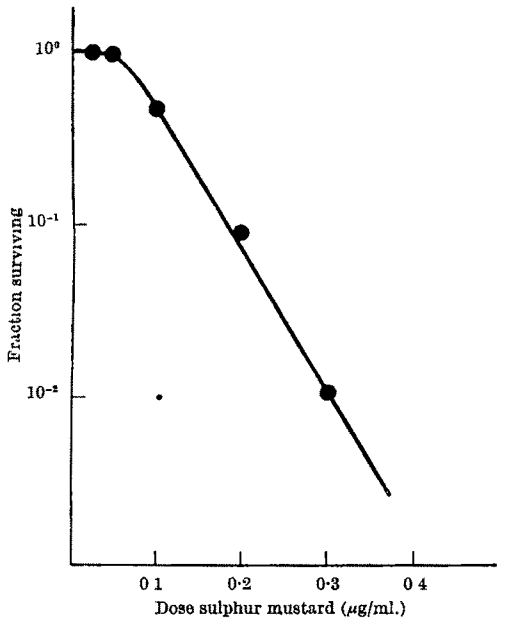

Fig. 1 Dose response of HeLa cell survival to sulphur mustard treatment. Method of derivation of the curve is described in the text

the cell cycle, which exhibit a difference in their sensitivity towards mustard gas, nevertheless reacted with [^{35}S]mustard gas to the same extent.

A logical explanation for these effects would be the existence of mechanisms capable of repairing the damage to DNA in cells less sensitive to the action of the mustard. Repair of damage to DNA could proceed by a sequence of steps which involves removal of the alkylated groups from alkylated DNA followed by subsequent degradation and resynthesis of a portion of the DNA. Evidence for an enzyme-mediated serial repair mechanism of this kind has been found in bacterial systems for the repair of damage caused by ultra-violet radiation[5,6], while it has been found that alkylated bases are excised from the DNA of *Escherichia coli B/r* following alkylation with mustard gas[7]. The purpose of this article is to present evidence that a mechanism exists in mammalian cells for the removal of alkylated bases from alkylated DNA.

Under conditions where extensive killing of cells occurs, the extent of reaction of the alkylating agent with DNA is very small ($\sim$ 1 alkylation per 10^5 nucleotides, see later) and it was considered that the only method having sufficient sensitivity to demonstrate a loss of alkyl groups from DNA of this kind would involve measurement of the change in specific radioactivity of DNA after alkylation with a labelled reagent. Despite the inhibition in the rate of DNA synthesis caused by mustard gas, DNA synthesis does proceed for many hours after administration of mustard and in cells which will not divide, so that the normal G_2 amount of DNA is synthesized[3,8]. Levis *et al.*[9] have reported that after human amnion cells (*AUP* strain) are treated with HN2 the DNA content per cell can reach much more than the G_2 level. Any loss in the specific radioactivity of DNA alkylated with labelled reagent could therefore be the consequence of an increase in the amount of DNA in the culture. In order to correct for any reduction in the specific radioactivity of the alkylated DNA due to continued DNA synthesis, cells were labelled with tritiated thymidine before they were treated with [^{35}S]mustard gas. Not only did this provide a method whereby one could allow for the dilution of the sulphur-35 label by subsequent DNA synthesis, but it also enabled the rate of DNA synthesis to be compared with that of a non-alkylated culture—this comparison is independent of the need for quantitative isolation of DNA.

For the present investigation, HeLa cells growing in suspension cultures were used. These cells had been found to have a sensitivity to mustard gas similar to that of the resistant line of mouse lymphoma cells previously investigated[3]. Their use presents the practical advantages that it is easier to grow large volumes of culture to high cell density ($\sim 10^6$/ml.) and that the DNA content per cell is greater ($1{\cdot}7 \times 10^{-11}$ g compared with $1{\cdot}2 \times 10^{-11}$ g). A dose-survival curve (Fig. 1) was obtained by normal plating procedures. Petri dishes (Falcon *TC*) were inoculated with an appropriate number of cells to give about 200 colonies per dish 30 min after treatment of the cells in suspension culture with various doses of mustard gas. Colonies were counted after 10 days' growth in a gassed incubator (95 per cent air, 5 per cent carbon dioxide). One factor which was observed, but not taken into account in the derivation of the curve, was the apparently slower rate of division of colonies derived from treated cells. For the purpose of constructing this curve, however, it was considered legitimate to count all visible colonies irrespective of apparent growth rate[10]. The dose for 37 per cent survival of the cells (D_0) was 0·05 μg/ml.—calculated from the straight portion of the survival curve (Fig. 1). As was the case with the resistant lymphoma cell line, the dose-response curve for the action of mustard gas on HeLa cells exhibits a shoulder which has been thought to be indicative of the operation of repair mechanisms[11].

In a typical experiment DNA was labelled by incubating HeLa cells (at a concentration of 4×10^5 cells/ml. growing in suspension culture in Eagle's medium) with tritiated thymidine at 5 mμc. (2 mμmole)/ml. After 24 h, the cells were transferred to the same volume of fresh medium for 6 h before half the culture was treated with [^{35}S]mustard gas at 0·32 μc. (0·5 μg)/ml. DNA, RNA and protein were then isolated after 45 min and at various times thereafter by the Kirby phenol method[12,13] from suitable measured portions of the mustard treated and control cultures (about 5×10^7 cells). The DNA was freed from any contaminating RNA by treatment with ribonuclease, then centrifuged in a mixture of 2 per cent sodium acetate and 1·5 per cent sodium chloride for 1 h at 64,000*g*. The following determinations were made at various times: the yields of DNA, RNA and protein in equal portions of control and treated cultures, the specific radioactivity of sulphur-35-labelled DNA, RNA and protein from mustard-treated cultures and the specific radioactivity of tritium-labelled DNA in treated and control cultures.

The results showed that the rate of synthesis of RNA and protein after mustard treatment, as indicated either by the increases in weights of material isolated (Fig. 2*b*) or by the decreases in their specific radioactivities (Fig. 2*a*), was the same as in the control culture. Furthermore, these syntheses proceeded at the same exponential rate as the increase in cell number of the control culture. This occurred despite the lack of increase in cell number of the mustard-treated culture which became, after 48 h, a uniform population of enlarged cells. The increase in the amount of DNA isolated from control cultures and the decrease in its specific radioactivity also proceeded at the same rate as the increase in cell number (Figs. 2*a* and *b*), thus providing evidence that in this system the thymidine was not being lost from the DNA owing to its turnover, or being re-utilized after such a loss. In mustard-treated cultures, however, there was a decrease in the rate of DNA synthesis as reflected by the slower rate of drop in the specific radioactivity of tritium-labelled DNA. This drop in rate of DNA synthesis has been confirmed by pulse-labelling experiments with [^{3}H]thymidine of high specific radioactivity for both HeLa and mouse lymphoma cells[3]. As this decrease occurred within 2 h of treatment with mustard, it could not have arisen from a mustard-induced mitotic block resulting in fewer cells entering the next synthetic period, contrary to the findings of Layde and Baserga for HN2-treated Ehrlich

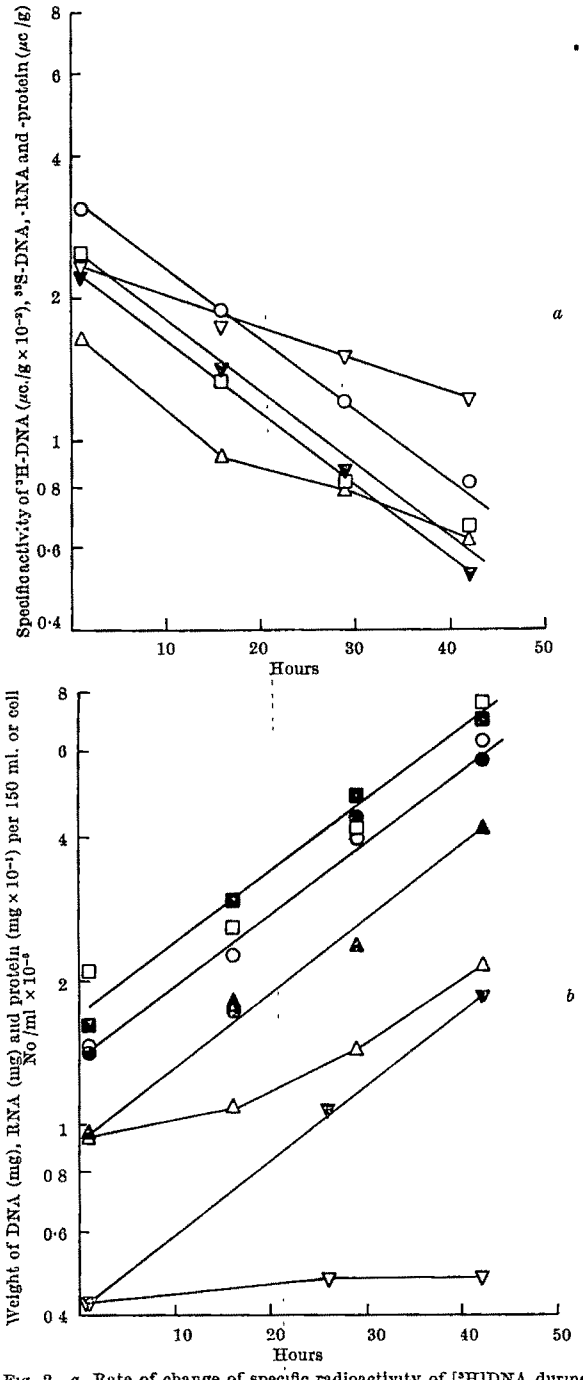

Fig 2. *a*, Rate of change of specific radioactivity of [³H]DNA during growth of HeLa cell culture and rate of change of specific radioactivity of [³⁵S] DNA, RNA and protein and [³H]DNA isolated from a similar HeLa cell culture after reaction with [³⁵S]mustard gas (0 5 μg (0 32 μc.)/ml.) A Packard 'Tricarb 3003' liquid scintillation spectrometer was used for all radioactive assays For the double-labelling experiments, settings were used such that in one channel tritium was counted at 18 5 per cent and sulphur-35 at 15 per cent while in a second channel tritium was 10^{-3} per cent and sulphur-35 29 per cent efficiencies. The specific radioactivities of DNA and RNA were corrected to an E_1^1 200 ▼, Tritiated DNA control; ▽, tritiated DNA mustard treated; △, sulphur-35 DNA mustard treated, □, sulphur-35 RNA mustard treated; ○, sulphur-35 protein mustard treated

ascites tumour cells[14]. The fact that the increase in total amount of DNA isolated paralleled this drop in specific radioactivity showed that either method of estimation was a true indication of net DNA synthesis and eliminated the possibility that any gross additional turnover of DNA occurred following alkylation. The loss of sulphur-35 label from DNA proceeded initially at a greater rate than the loss of tritium label from DNA, which indicated that a loss of the alkylated groups from DNA had occurred and had been accompanied by, or was a prerequisite for, continued DNA synthesis. The increase in yield of DNA could be calculated from the decrease in the specific radioactivity of the tritium in DNA, and from this and from the drop in specific radioactivity of the sulphur-35 label in the same DNA a value for the absolute loss of alkylating agent residues from DNA was derived. Three such experiments were carried out under these conditions of mustard treatment and gave essentially the same result of an overall loss of sulphur-35 label from DNA of about 50 per cent (Fig. 3, II, III and V). A fourth experiment (Fig. 3, IV) was also performed in which the pre-labelled HeLa cells were treated with unlabelled mustard gas (0·25 μg/ml.) and unlabelled cells were treated with the same concentration of [³⁵S]mustard gas. The changes in radioactivity due to tritium and sulphur-35 in the DNAs isolated after various times were combined, as with the double-labelling experiments, to give the percentage loss of sulphur-35 radioactivity (the sulphur-35 labelled DNA was used for the chromatography discussed later (Fig. 4)). It is evident that the major portion of this loss had occurred within the first cell generation time after treatment, and that the rate of loss decreased with time. At present there is insufficient evidence to indicate either the precise time-course for the reaction or its dependence on dose.

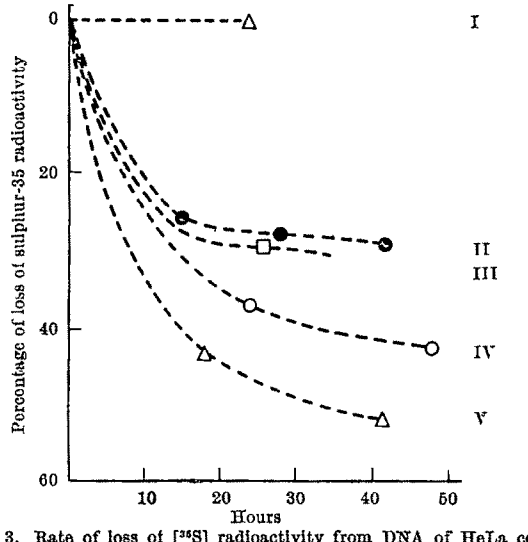

Fig. 3. Rate of loss of [³⁵S] radioactivity from DNA of HeLa cells following their reaction with various doses of [³⁵S]mustard gas. Loss of radioactivity was calculated from changes in [³H] and [³⁵S] specific radioactivity of DNA as illustrated in Fig. 2*a* and described in text. Curve II corresponds to data in Fig. 2*a* and *b*. I, 0·25 μg/ml. + IAA; II, 0·5 μg/ml.; III, 0 5 μg/ml ; IV, 0·25 μg/ml ; V, 0 4 μg/ml.

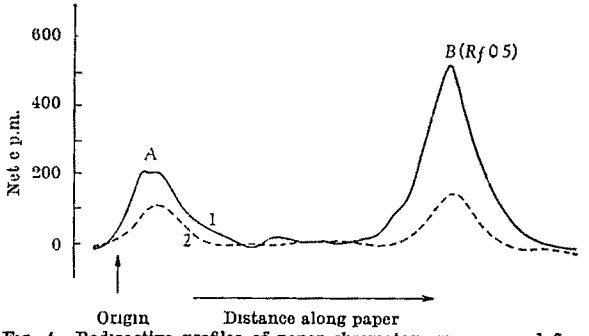

Fig 4. Radioactive profiles of paper chromatograms prepared from radioactive DNA (2 mg and not less than 4 mμc) isolated from a HeLa cell culture 0 5 h (1) and 48 h (2) after treatment with [³⁵S]mustard gas (0·25 μg (0 4 μc.)/ml.), and heated in N hydrochloric acid (1 mg/0 05 ml.) at 100° C for 0·25 h Papers were developed by downflow chromatography with isopropanol–conc. hydrochloric acid–water (78 : 16·4 : 15·6) for 18 h

That the loss of mustard from DNA was enzymatically mediated and did not arise from spontaneous hydrolysis of alkylated DNA[15] was indicated by the fact that it could be inhibited by iodoacetamide under conditions where DNA synthesis did not occur. Cells (2×10^8/500 ml.) which had been treated 0·5 h previously with [^{35}S]-mustard gas (0·25 μg/ml.) were disrupted by the method of Rosenberg and Cavalieri[16]. DNA was isolated from half the cell lysate (2·5 ml.) while the remainder was placed in a dialysis bag with 0·5 mM iodoacetamide and dialysed at 37° C overnight against 500 ml. of Eagle's medium. The specific radioactivity of the sulphur-35-labelled DNA which was later isolated was the same as that isolated initially (Fig. 3, I).

It has been established[1] that, at low levels of reaction, mustard gas reacts preferentially with guanine moieties of DNA. A proportion of the mustard reacts with two guanine moieties in adjacent base pairs, and it is thought that these lie in opposite strands of the macromolecular structure: it is this latter reaction which is supposedly responsible for the cytotoxic action of mustard gas. The preferential removal of these cross-links in the form of di(guanin-7-yl)ethyl sulphide has been shown by Lawley and Brookes[7] to be associated with resistance to mustard gas in *E. coli* strain *B/r*. Clearly it was of interest to determine whether the loss of mustard from the DNA of mammalian cells occurred in an analogous preferential manner. Accordingly, DNA isolated from cultures 45 min and 48 h after mustard treatment was hydrolysed with N hydrochloric acid and chromatographed on Whatman No. 1 paper.

The distribution of radioactivity on the paper was determined using a Nuclear Chicago 'Actigraph II' chromatogram-scanner and revealed the usual pattern of two radioactive products for 2-hydroxyethylthioethyl-guanine (*B* in Fig. 4) and at the origin the cross-linked product, di-(guanin-7-yl)ethyl sulphide (*A* in Fig. 4)—the latter present initially to the extent of 26 per cent of the total radioactivity on the paper. In DNA isolated after 48 h, the proportion of this product on chromatograms had increased to 34 per cent of the total. While the quantitative aspects of this phenomenon need further investigation, nevertheless some preliminary conclusions can be drawn from the result.

If it is assumed that all product *A* results from inter-strand cross-linking, then three simple modes of action for a possible excision mechanism can be considered:

(1) Exclusive excision of cross-linked material. This would lead to a maximum loss of activity in the experiments described of 26 per cent with a complete elimination of spot *A*.

(2) Excision occurring on only one strand of DNA. This would lead, if all alkylated bases were removed, to a loss of activity of 37 per cent and an increase in the percentage of compound *A* to 40 per cent.

(3) Completely random excision from both chains of the DNA, with the additional assumption that removal of an alkylated base from one chain does not affect the probability of the subsequent removal of the cross-linked base on the other chain. From these assumptions, if half compound *B* is removed, then a quarter of compound *A* is also removed, and a loss of 44 per cent of the total activity results in an increase in the proportion of *A* to 33 per cent.

The experimental value obtained of a reduction of 43 per cent in total sulphur-35 label in DNA accompanied by an increase in the proportion of *A* from 26 to 34 per cent agrees best with mechanism (3), although the errors inherent in deriving values from the chromatograms would not preclude mechanism (2). It is apparent, however, that the mechanism of excision of alkylated groups from DNA in mammalian cells as described here differs from that reported for the removal of alkylated bases from *E. coli B/r* (ref. 7) in which the cross-linked material is preferentially removed.

These investigations with a radioactive alkylating agent permit a calculation of the amount of reaction occurring with HeLa cell DNA in relation to the dose of mustard gas given and a comparison can be made with other published values[4]. The lethal dose of mustard gas can further be compared with that of X-rays. At a dose of 0·5 μg/ml. the results show that one molecule of mustard gas reacts per $1·3 \times 10^5$ molecules of DNA-P, and at the D_0 value obtained from Fig. 1 of 0·05 μg/ml. the amount of reaction would therefore be 1 molecule per $1·3 \times 10^6$ molecules DNA-P. As there are 3×10^{10} DNA-P atoms in the HeLa nucleus this is equivalent to $2·3 \times 10^4$ alkylations in the total cellular DNA. The corresponding value for either mouse *L* cells[4] or mouse lymphoma cells is 4×10^4 (ref. 17). Assuming that, as already discussed, 25 per cent of the reaction of mustard gas with HeLa cell DNA leads to cross-links which are the assumed lesions, then the overall reaction is equivalent to $5·7 \times 10^3$ cross-links in the total cellular DNA. It has been calculated[18,19] that for ionizing radiation the D_0 value is equivalent to one ionization per DNA of molecular weight 10^9–10^{10}, or 10^3–10^4 total hits per cell. This value is therefore of the same order as the number of mustard cross-links per cell, and this comparison thus lends support to the view that DNA is the target for both agents. The extent of reaction with RNA or protein molecules would in both cases be very small, because the molecular weight of these is much less than that of DNA and there is no evidence for anything other than random attack on all cellular constituents. If the existence of the shoulder in the survival curve (Fig. 1) is indicative of a repair mechanism[11], then this repair mechanism is saturated at a dose of 0·07 μg/ml. which corresponds to 8×10^3 DNA cross-links per cell.

Furthermore, the sole biochemical action of mustard gas at a dose about equal to the D_0 value detected in these experiments on HeLa cells was a depression in the rate of DNA synthesis, and this depression was a prelude to the premitotic block which ensued and was not a consequence of it. Similar findings have been reported for the action of similarly low doses of X-rays[18,19]. For both cytotoxic agents it is therefore indicated that the lethal damage is the result of direct effect on the DNA which interferes with its replicative ability, but not with its function as a template for RNA synthesis at the low doses capable of preventing cell division.

We thank Prof. A. Haddow and Prof. J. A. V. Butler for their interest and encouragement in this work, Dr. P. D. Lawley for much helpful discussion and Miss Ann Stephenson and Mrs. Lorna Willcox for technical assistance. This investigation has been supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council and the British Empire Cancer Campaign for Research, and by a U.S. Public Health Service research grant from the National Cancer Institute.

RIBONUCLEIC ACID SYNTHESIS IN MACROPHAGES IN RELATION TO THE SECONDARY IMMUNE RESPONSE *IN VITRO*

By DR. GILMOUR HARRIS*

Experimental Radiopathology Research Unit and Department of Medicine, Postgraduate Medical School, Hammersmith Hospital, London

RECENT investigations have suggested that macrophages take an intermediary role in the mechanism of antibody formation, and most investigations of the fate of antigens have indicated that they are taken up by phagocytic cells in spleen and lymphoid tissues, and in various other organs including the liver[1–3], where they have been reported as complexed with nucleic acids[4].

Fishman and Adler[5] reported that phenol extracts of ribonucleic acid (RNA) from macrophages after contact with bacteriophage induced phage-neutralizing antibodies when added to lymphoid cells in tissue culture or transplantation chambers. They concluded that the material was most likely to be a low-molecular-weight RNA, and further investigation indicated that such an RNA from macrophages was incorporated by lymph node cells[6]. In all these experiments, the RNA was extracted from cell preparations consisting largely of macrophages, but cell-transfer studies[7] with similar preparations showed that potential antibody-forming cells were also present.

Haemocyanin was used as an antigen in mice[8] to find whether macrophages actively process antigens as a necessary step in the induction of the immune response. It was concluded that RNA preparations from mouse peritoneal cells after uptake of haemocyanin labelled with iodine-131 *in vivo* were immunogenic in primed mice, but the RNA contained radioactivity with properties compatible with the antigen or fragments thereof, and the preparations were found to be more immunogenic than original antigen.

A recent short report[9] has indicated that preparations of bovine serum albumin (BSA) after "biological filtering", by injecting into intact, non-immunized rabbits and taking the serum after an interval to inject into fresh animals, had lost its ability to stimulate an antibody response and some of the rabbits injected with filtered BSA became tolerant to it. The authors suggested that macrophages played a part in the immune response and that processing of antigens by these cells was necessary for the synthesis of antibody. A recent investigation[10] using autoradiography combined with electron microscopy has shown that iodine-125-labelled *Salmonella* flagellar protein was present on the surface of the dendritic macrophages of the lymphoid follicles, perhaps bringing the antigen into close contact with the responsive cells.

It has been found that peritoneal exudate cells induced in normal rabbits by intraperitoneal injections of oyster glycogen and triolein can take up heterologous proteins and that these primed cells can stimulate the rate of DNA synthesis in spleen cells from rabbits immunized to the specific antigen[11]. This response was antigen-specific and was considered to be an *in vitro* manifestation of the secondary immune response. Using this system, investigations of the role of RNA synthesis in peritoneal cells in relation to this transfer mechanism were carried out.

Methods for obtaining spleen cell suspensions[12] and macrophages[11] have been described in detail, DNA synthesis in spleen cells being measured by the incorporation of carbon-14-labelled thymidine during 24–48 h of culture[12]. RNA synthesis in macrophages was measured by the incorporation of tritiated uridine. Uptake of protein by macrophages was measured by the incorporation of iodine-131-labelled human serum albumin (HSA). All radioactive materials were obtained from the Radiochemical Centre, Amersham.

When 1×10^6 peritoneal exudate cells were incubated in tritiated uridine for 8-h periods and the rate of incorporation was measured (Fig. 1), the peak of uridine incorporation was maximal at about 20 h of culture and then fell to zero by 44 h. No effect, due to the presence of heterologous protein, was noted in these experiments.

Actinomycin-*D* (Act-*D*) obtained from Merck, Sharp and Dohme, Ltd., Rahway, New Jersey, was used to inhibit uridine incorporation, and typical results are shown in Fig. 2. No effect was seen during the first 24 h of culture until the concentration of Act-*D* was more than 10^{-5} μg/ml. in the medium, while lower concentrations produced some inhibition when uptake of tritiated uridine was measured over 48 h of culture

Table 1 illustrates that inhibition by Act-*D* was time-dependent and that the effect was not reversed by washing the cells and incubating in the absence of Act-*D* for up to 48 h.

The results in Table 2 show that the presence of Act-*D* in the medium in concentrations sufficient to inhibit significantly the incorporation of tritiated uridine into macrophages did not affect their ability to transfer an antigen-specific response to spleen cells from an immunized rabbit. Pre-incubation of macrophages in Act-*D*

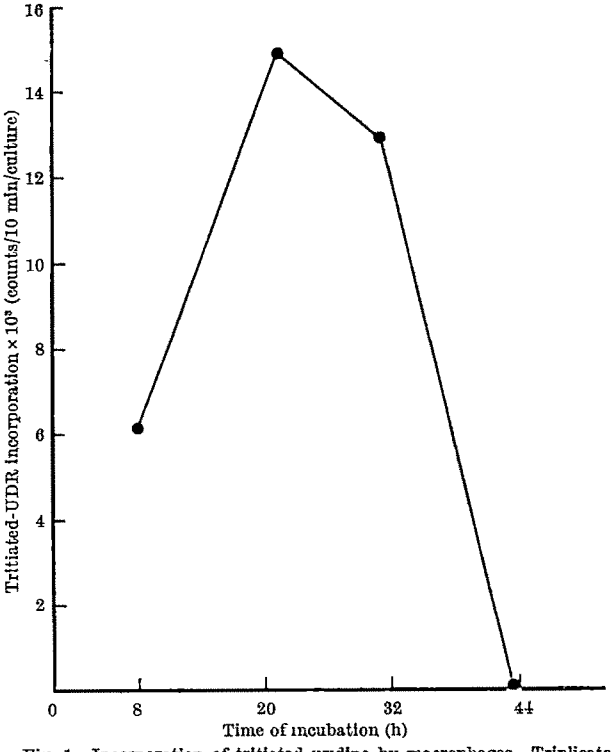

Fig. 1. Incorporation of tritiated uridine by macrophages. Triplicate cultures of 1×10^6 cells were incubated with 5 μc./ml. of tritiated uridine (200 mc./mM) for periods of 8 h. After washing in warm medium, the cells were removed from the culture beaker with cold 0·02 per cent sodium versenate, washed in ice-cold 5 per cent TCA, the precipitates washed in cold methanol, and dissolved in hyamine for measurement of radioactivity by scintillation counting

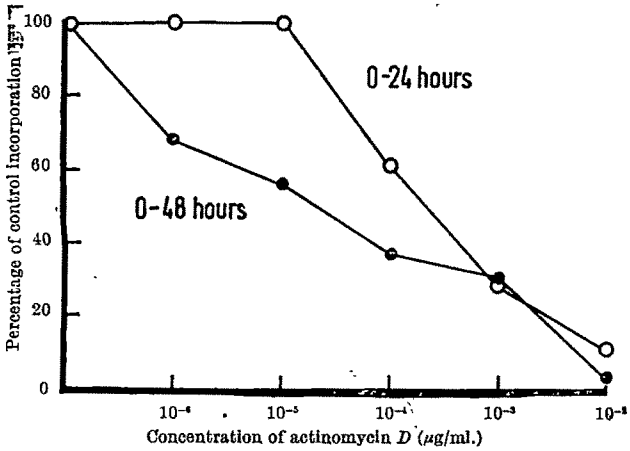

Fig. 2. Inhibition of tritiated uridine incorporation into macrophages by actinomycin-*D*. Act-*D* and tritiated uridine were added initially and uridine incorporation measured as in Fig. 1

for 6 h before exposing them to antigen also failed to prevent this transfer, and, as shown in Table 3, Act-*D* does not influence the uptake of iodine-131-labelled HSA by macrophages. Similar experiments using RNA preparations extracted with phenol[13] from macrophages incubated with antigen have all been negative. Intact macrophages were necessary for positive results although cells, heat-killed or irradiated with a dose of 2,000 rads after incubation in antigen, could still stimulate responsive cells.

The results presented here indicate that macrophages from peritoneal exudates took up antigen and transferred its specific stimulation of the rate of DNA synthesis in spleen cells from an immunized rabbit. If RNA played a part in this process it was unlikely to be that of a specific template produced by macrophages after contact with antigen. Other investigations[11] have shown that antigen was present on the surfaces of primed cells and that antibody to antigen could block transfer. It is therefore tentatively concluded that the role of macrophages in the stimulation of cell proliferation in the immune response is to take up antigen on to their cell surfaces, where it plays some part in the regulation of lymphoid cell proliferation. The mechanism of this is obscure. Previous investigations[11] have not been able to establish any evidence of direct contact of the dividing cells with macrophages. Of course, it is still possible that macrophages produce an informational RNA molecule which can direct the specificity of antibody formation in cells synthesizing immunoglobulins. This possibility is being further explored. The experiments presented here were only concerned with the mechanism of stimulation of cell division in response to antigen.

Table 1. Inhibition of Tritiated Uridine Incorporation by Macrophages in Relation to Time of Contact with Act-*D*

Time of contact with Act-*D*	RNA synthesis (counts/10 min/culture)					
	Time of wash–24 h		24–48 h		Time of wash–48 h	
1×10^{-2} μg/ml.	Act-*D*	Control	Act-*D*	Control	Act-*D*	Control
1 h	2,464	4,006	15,565	23,626	2,408	3,768
3 h	1,070	7,663	6,172	23,968	1,251	11,124
6 h	1,024	12,635	2,033	26,141	1,308	10,854
24 h	429	8,615	29	24,548	29	24,548

Macrophages were incubated in Act-*D*, then washed in warm medium and the incorporation of uridine was measured as described in Fig. 1.

Table 2. Effect of Act-*D* on the Ability of Macrophages primed with Antigen to stimulate Spleen Cells

Act-*D* (μg/ml.)	DNA synthesis rate (counts/min/culture)			
	C	*C* + *M*(*C*)	HGG	*C* + *M*(HGG)
0	560	547	15,220	5,076
1×10^{-6}	—	433	—	3,925
1×10^{-5}	—	600	—	4,465
1×10^{-4}	—	503	—	4,360
1×10^{-3}	—	543	—	4,786
1×10^{-2}	—	560	—	4,790

Cultures of 1×10^5 macrophages were incubated in Act-*D* (*M*(*C*)) or Act-*D* and HGG (*M*(HGG)) for 18 h, washed three times in warm medium, and 1×10^7 spleen cells from a rabbit immunized to HGG were added. The rate of DNA synthesis in the spleen cells was measured by the incorporation of carbon-14-labelled thymidine during the 24–48 h after adding the spleen cells to the macrophages.

Table 3. Uptake of Iodine-131-labelled HSA by Macrophages in the Presence of Act-*D*

Act-*D* (μg/ml.)	Uptake of HSA (counts/min/culture)
0	3,990
1×10^{-4}	4,883
1×10^{-3}	3,630
1×10^{-2}	3,170
1×10^{-1}	3,775

Triplicate cultures of 1×10^6 macrophages were incubated in the presence of iodine-131-labelled HSA and Act-*D* for 24 h, washed three times in ice-cold saline and dissolved in 6 *N* hydrochloric acid for gas-flow counting.

AN EARLIER PHASE OF THE LIGHT-EVOKED ELECTRICAL RESPONSE FROM THE PIGMENT EPITHELIUM-CHOROID COMPLEX OF THE EYE OF THE TOAD

By Dr. KENNETH T. BROWN* and Dr. PETER W. GAGE†

Department of Physiology, Australian National University, Canberra

An extremely rapid biphasic response has been found which is evoked by light from the retinal photo-receptors of the monkey, and which has been designated the early receptor potential[1–3]. This type of response has also been found in a number of other vertebrate species[4,5]. Its second phase may be selectively abolished by either lowered temperature[6] or light adaptation[5], so the two phases of the early receptor potential are separately generated. The early receptor potential is followed by a much slower response called the late receptor potential[1,3], which may be selectively abolished by anoxia[1]. Thus the response of the retinal photoreceptors consists of three separate phases. More recently, it has been shown that the pigment epithelium-choroid complex of the eye of the toad contains photosensitive cells which generate an electrical response to light stimuli[5]. For convenience, this type of response will be referred to in the present article as the 'non-retinal response'. It seems evident that the cells which generate the non-retinal response are not as specialized for light detection as the retinal rods and cones. This provides an opportunity to compare the responses from retinal photoreceptors with those from

* Permanent address: Department of Physiology, University of California Medical Center, San Francisco, California.

† Present address: Department of Physiology and Pharmacology, Duke University Medical Center, Durham, North Carolina.

a more primitive type of photosensitive cell. The non-retinal response was first described as biphasic in form, and its latency was about 25–30 μsec[5]. We have now found an earlier phase of the non-retinal response which has no detectable latency. Thus the non-retinal response likewise contains three phases, which we have separated by appropriate procedures, and evidence is presented which indicates that the three phases of the non-retinal response are comparable with those generated by retinal photoreceptors. These findings greatly increase the probability that a fundamental sequence of electrical responses has been found which occurs in many or all types of photosensitive cells within the animal kingdom.

The general methods for this work have been described previously in detail[5]. Briefly, the eye was enucleated from the toad (*Bufo marinus*). The front of the eye was then cut away, and the retina was removed from the eye cup with a piece of dry cotton. The remaining eye cup consisted only of the pigment epithelium-choroid complex, which was supported by the sclera. This eye cup was set on a cotton wick soaked with frog Ringer's solution, which acted as the reference electrode. A second cotton-wick electrode made contact with Ringer's solution inside the eye cup. The polarity of all records was such that an upward deflexion indicated positivity of the inner side of the eye cup. The frequency of the recording system was flat over the range 6–60,000 c/s, which was sufficient to give undistorted responses. Light stimuli were provided by a condenser-discharge lamp (Honeywell 'Strobonar 65C'), which gave an intense flash having an effective duration of 0·7 msec. This lamp was mounted outside the electrically shielded recording room, and the light was led to the preparation by a fibre optics bundle, one end of which was placed close to the flash tube, and the other mounted directly over the eye cup. Both electric and photoelectric artefacts were completely absent from the records, except when introduced deliberately for timing purposes. The preparation was mounted in a small flat-bottomed glass dish, which was partially submerged in a water bath, the temperature of which could be held constant or varied. The temperature of the preparation was monitored by a small thermistor probe in the Ringer's solution inside the eye cup.

Fig. 1 shows the major effects of lowered temperature on the non-retinal response, and these effects have all been observed consistently in many experiments. The response at 24·5° C consisted of a rapid negative phase, followed by a slower positive phase. These are the two phases reported previously at room temperatures[5], and they comprise the second and third phases of the total response. When the temperature was lowered to 16·5° C, the positive third phase was decreased in amplitude; also its peak occurred at a later time, and the response was broadened. By comparison, the negative second phase showed a distinct increase in amplitude. The different sensitivities of the second and third phases to lowered temperature strongly suggest that they are generated by different mechanisms, and the apparent increase of the negative second phase is probably due to the greater effect of lowered temperature on the positive third phase. When the temperature was lowered to 7° C, the effects on the third phase became more marked. The second phase showed a slight further increase in amplitude, while its peak was delayed and its time course broadened. Also at this temperature a positive first phase became apparent. When the temperature was further lowered to 2·5° C, the negative second phase became smaller and markedly slower in its time course, and the positive first phase became even more prominent. Thus the total response contains an initial positive phase, which normally is masked by the negative second phase. Because this masking occurs, and results in a normal response with a clearly measurable latency, the second phase must normally begin at the same time as the first phase or very shortly thereafter. Lowered temperature affects the second phase more than the first; thus as the negative second phase is slowed in its time course, and reduced in amplitude, the initial positive phase is progressively revealed. Because the second phase is more temperature-dependent than the first phase, these two phases also appear to be generated separately. The effects of lowered temperature on the first and second phases of the non-retinal response are closely analogous to those found by Pak and Cone for the early receptor potential of the whole eye of the rat[6]. In their work on the rat an initial positive phase of the early receptor potential was not seen clearly at room temperatures, but was revealed by lowered temperature as the negative second phase was decreased in amplitude and slowed in

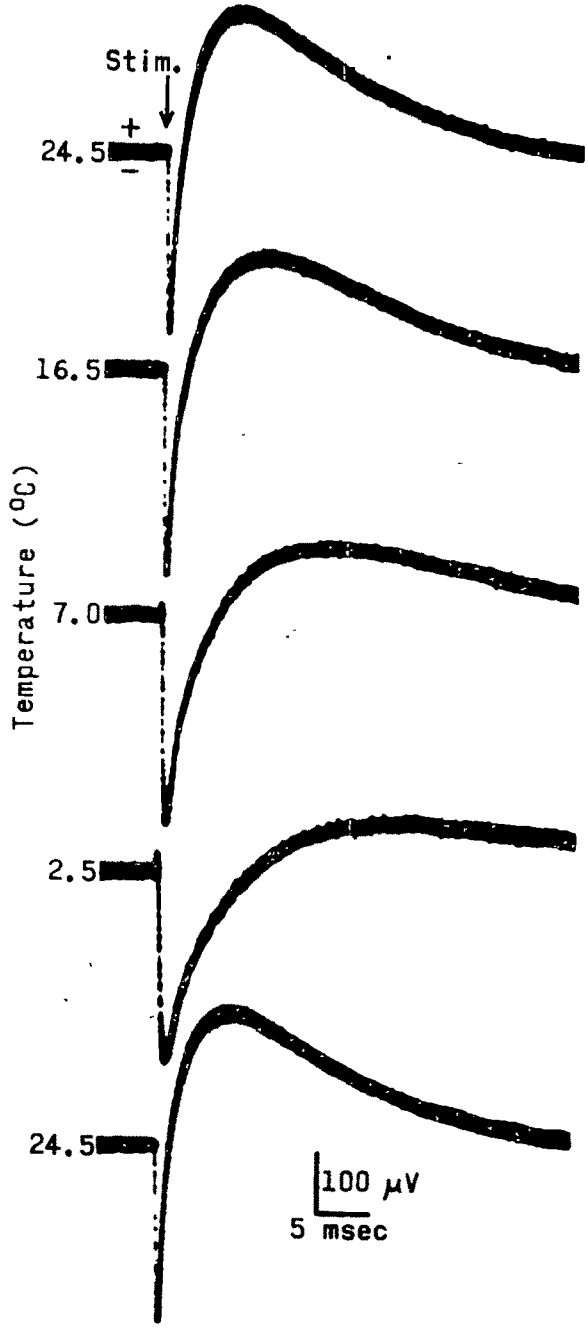

Fig. 1. The effect of lowered temperature on the non-retinal response. The temperature was first lowered, and representative records are shown reading from the top downward; the temperature was then returned to the control value, as shown by the bottom record. Stimuli were delivered at 1-min intervals for 5 min before this series of records, and throughout the series of records, in order to maintain constant light adaptation. The time of delivery of the stimulus is shown by an arrow over the top record

its time course. The first phase was essentially isolated at about 0° C, and Pak and Ebrey[7] found that the first phase could be detected at temperatures as low as −35° C.

In certain experiments we lowered the temperature of the preparation as far as −8° C. Glycerol was used in the wicks to prevent freezing, but was not added to the solution in the eye cup because it shrinks cells. Within this sub-zero range, progressive effects of lowered temperature were noted which were qualitatively similar to those shown in Fig. 1. At −8° C the third phase was extremely slowed and had almost disappeared, while the second phase was much smaller and broader; the first phase was larger, but at this temperature it was still not so large as the second phase. Thus lowered temperature might isolate the first phase of the non-retinal response, but in this case the temperatures required are inconveniently far below 0° C.

While investigating the non-retinal response at sub-zero temperatures, the introduction of Ringer's solution and glycerol (1 : 1) into the eye cup caused a reduction in amplitude of both the second and third phases of the response. This occurred within a few seconds, revealing an initial positive phase. The second and third phases sometimes recovered gradually, but incompletely, over a period of several minutes. It seemed likely that these effects were due to the high osmotic pressure of the glycerol solution, which initially dehydrated the photosensitive cells, with gradual penetration of the glycerol into the cells resulting in re-hydration and partial recovery of the response in some cases. If this interpretation were correct, the initial positive phase should be isolated stably by increasing the extracellular osmotic pressure with biologically inert substances which do not penetrate cell membranes. For this purpose we tried Ringer's solutions containing polyethylene glycol ('Carbowax, 1500') and having osmotic pressures above 1,000 mosmols. Fig. 2 shows the sequence of effects when 'Carbowax' Ringer's was introduced into the eye cup. The third phase was reduced more rapidly than the second phase, as shown in record 2. Then the third phase disappeared, as shown in record 3, at which time the second phase was greatly reduced and the initial positive phase was revealed. In record 4 the second phase has also disappeared, and the initial positive phase appears to be isolated. The different sensitivities of the three phases of the response to this procedure provide another type of evidence that the three phases are generated by somewhat different mechanisms. As shown by record 5, the isolated first phase of the response has no detectable latency. It would seem that the latency of this first phase could not exceed a few μsec, which is comparable with that of the first phase of the early receptor potential of the toad retina[5].

When Ringer's solution was saturated with sucrose, similar results were obtained. Also if the preparation was allowed to dry by standing in air for several hours, and if a wick electrode was then inserted into the eye cup without adding fluid, the response consisted only of a small initial positive potential. Thus any method of removing the intracellular fluid seems to isolate the first phase. With 'Carbowax' Ringer's the form and amplitude of the isolated first phase have been stably maintained for at least 15 min. This was sufficient for our experiments, so longer periods were not attempted. Thus, 'Carbowax' provides a simple and effective method for isolating the initial positive phase, and for maintaining it stably so that some systematic experiments may be performed on it.

When the pigment epithelium-choroid complex was removed from the preparation, and the sclera was partially filled with 'Carbowax' Ringer's, no response was detected. Also no response was recorded when the wick electrodes were in direct contact. Similar controls have been performed for the second and third phases of the response[5]. Thus all three phases of the non-retinal response are generated bioelectrically within the pigment epithelium-choroid complex. The non-retinal response of the frog has been recorded recently by micropipette electrodes in the pigment epithelial cells, which lie immediately at the surface of the eye cup preparation[8]. Both the first and second phases of the response are inverted in these intracellular records, so the non-retinal response appears to be generated by the cells of the pigment epithelium.

The non-retinal response is so resistant to light adaptation that true effects of light adaptation were not clearly demonstrated in the initial report[5]. We have now found that during a sequence of maximum intensity flashes at 15-sec intervals, both the second and third phases decrease slightly in amplitude; initial amplitude is then recovered after dark adaptation. Following isolation of the first phase by 'Carbowax' Ringer's, a similar schedule of stimulation and dark adaptation produces similar effects on the amplitude of the first phase. Thus all three phases of the response show quite small effects of light adaptation. This is in contrast with responses of the toad's retinal photoreceptors, which show marked effects of light adaptation[5]. An important question is whether all three phases of the non-retinal response result from the absorption of light by a single type of photopigment. Because resistance to light adaptation is a unique property of this response, the similar small effects of light adaptation

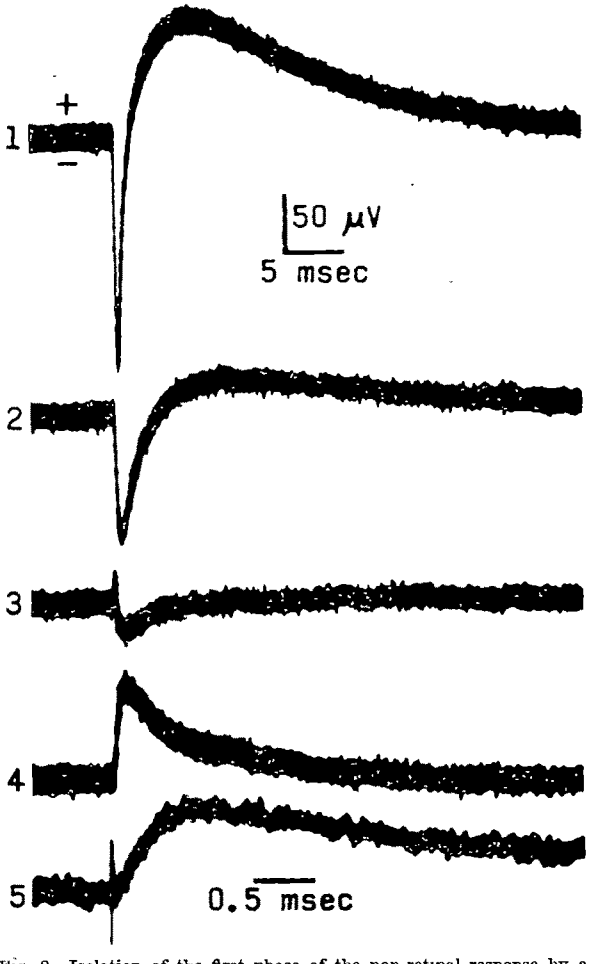

Fig. 2. Isolation of the first phase of the non-retinal response by a hypertonic extracellular medium. Record 1 is a control response with Ringer's solution in the eye cup. Then the Ringer's solution was sucked out and a Ringer's solution containing 'Carbowax' was introduced (see text). Record 2 was taken about 20 sec after this procedure, and record 3 was taken after 170 sec. Record 4 shows the final effect in a different preparation, in which 'Carbowax' Ringer's gave an isolated initial phase which was particularly large, and record 5 shows this isolated first phase at higher sweep speed. In record 5 a stimulus artefact, which resulted from discharge of the condenser in the light source, was introduced deliberately for timing purposes, it was recorded as a vertical line, and the response rises immediately after the artefact. During these records the stimulus was repeated at 15-sec intervals, for control of light adaptation, and the temperature was about 25° C

on the three phases are strong evidence that the three phases result from the absorption of light by a single type of photopigment. Recent results indicate that this pigment is melanin. The response which resists light adaptation is large and readily demonstrated in the eyes of pigmented rats, while a superficially similar but smaller response from the eyes of albino rats[5] now seems to be due to the early receptor potential. These findings were first made by Arden[9], and have been confirmed by Brown and Crawford[8].

We also observed the effects of lowering the temperature on receptor responses in the isolated retina of the toad, using previously described methods of isolating the retina and recording from it[5]. This was done in order to compare the effects of lowered temperature on the retinal responses with effects on the non-retinal responses of the same animal. The *a*-wave of the electroretinogram, which results from the rise of the late receptor potential[3], disappeared when the temperature was reduced to the range of 5°–9° C. Further reduction of temperature eliminated the second phase of the early receptor potential and isolated the first phase; this occurred at about 0° C. Thus the three phases of the response from retinal photoreceptors show a similar order of temperature-dependence. But the second and third phases of the retinal response do not survive to such low temperatures as analogous phases of the non-retinal response in the same species.

In both the retinal and non-retinal responses, the first and second phases are quite rapid by comparison with the slower third phase. But at room temperature the second phase of the non-retinal response attains its peak after about 0·3 msec, while the second phase of the early receptor potential of the toad occurs after about 1·75 msec[5]. Also the third phase of the non-retinal response must begin after less than 0·3 msec, because its amplitude can affect the measured amplitude of the second phase, while the late receptor potential of the toad's retina does not seem to begin until after at least 5 msec. Thus the second and third phases of the retinal response appear to be slower than analogous phases of the non-retinal response. Of several possible explanations for this, one is the greater length of the retinal photoreceptors. The first two phases of the non-retinal response have the same polarity as the two phases of the early receptor potential. But the third phase of the non-retinal response is positive, while the late receptor potential is negative, when recorded under comparable conditions, This is an intriguing point which requires further investigation.

The entire non-retinal response was well supported by placing either 0·9 per cent sodium chloride or frog Ringer's in the eye cup. When the sodium chloride in the Ringer's solution was replaced by sodium nitrate, there was no distinct effect. But when the sodium chloride was replaced osmotically by sucrose or lithium chloride, the third phase was reduced in amplitude within 1 or 2 min and then abolished. Thus the third phase is dependent on sodium ions in the eye-cup solution. Also ouabain (5×10^{-4} M), which depresses active transport of sodium across cell membranes[10], slowly and selectively reduced the amplitude of the third phase. This suggests that the third phase is dependent on an active transport of sodium ions. But the second phase seems insensitive to the ionic composibion of the eye-cup solution, and the first phase can even withstand dehydration of the cells. In these respects, also, the non-retinal response seems comparable with responses of retinal receptors. The *a*-wave of the electroretinogram, which serves as an index of the late receptor potential, is critically dependent on sodium ions[11,12]. It is also abolished by high potassium concentrations, which presumably depolarize the retinal receptors[13]. On the other hand, the early receptor potential is not affected by the ionic composition of the bathing medium[13,14].

Thus the findings reported in this article greatly increase the likelihood that the sequence of electrical responses in retinal photoreceptors is a fundamental one which occurs also in a more primitive type of photosensitive cell in the pigment epithelium-choroid complex. It seems possible to explain readily the detailed differences which have been noted on the basis of differences in the absorbing photopigments or in the generating cells. Thus the two response sequences seem to represent variations on a basic theme, as expected if a fundamental response sequence is investigated in photoreceptors at different levels of specialization. In this sequence it seems very likely that the first phase is generated by a solid-state potential. It survives dehydration of the cells, is not affected by the ionic composition of the bathing medium, and has a very low temperature-dependence which permits its survival well into the sub-zero range. The general possibility of solid-state potentials in excitable cells has already been suggested[15–17], and this type of potential would now seem to have been found in photoreceptors. The characteristics of the second phase are rather transitional between those of the first and third phases, and the third phase appears to result from a transmembrane ion flux.

During this work, one of us (K. T. B.) was a Fellow of the Commonwealth Fund, on sabbatical leave of absence from the University of California Medical Center in San Francisco. This work was also supported in part by a grant from the National Institute of Neurological Diseases and Blindness, U.S. Public Health Service.

BIREFRINGENCE OF DIAMOND

By PROF. S. TOLANSKY
Royal Holloway College, University of London, Egham, Surrey

IT is generally considered, both from its morphology and etching figures, that diamond belongs to the holohedral cubic system and that it should not show birefringence unless strained. Yet it has been common knowledge since 1815, when Brewster described double refraction in some diamonds, that many diamonds are, in fact, birefringent. It has generally been assumed that these were strained either during growth or later. There have been conflicting views as to how widespread is this diamond birefringence. The most significant contribution to this subject is that of G. Friedel[1], who described a polariscope investigation of 200 diamonds and of 150 thin cleavage sheets. He reported that all the crystals showed some degree of birefringence and that so also did many of the cleavages.

In the extensive literature dealing with the diamond, very little has been published concerning terrestrial micro-diamonds, if we call as such (quite arbitrarily) diamonds smaller than 0·2 mm across. With the advent of some millions of carats of synthetic diamond of just this size, it is now of interest to compare the properties of synthetic diamond with natural diamond of comparable size. In the standard grease-table recovery technique used at diamond mines, quantities of small-mesh tailings are collected, but it is not economic or useful to sort this material. I have acquired 350 carats of small-mesh South African mine tailings and a search through this has yielded 3,000 clear transparent well-formed micro-diamonds. They are present in the tailings to the extent of a fraction of 1 per cent, the rest being breakage fragments from much larger crystals.

These small whole crystals are about equally divided between octahedra, dodecahedra and triangular twins. There are no cubes, which is in conformity with usual South African experience. Some 10 per cent of the octahedra show a small black inclusion. Inclusions are quite rare in both the dodecahedra and the triangular twins. These crystals are now being investigated from the point of view of determining their morphology, surface micro-topography, fluorescence and birefringence. This report will deal only with their birefringence.

Surprisingly enough, without exception, all 3,000 exhibited birefringence. Despite the small thickness, in most, the double refraction can be fairly large, and frequently several bands appeared under the polarizing microscope. Observations were deliberately made with a light source of only moderate intensity, so that any near approach to extinction would not be over-illuminated. The occurrence of birefringence in all these small, clear, well-formed crystals was so unexpected that arrangements were made with the central diamond distributing organization (Industrial Distributors) to examine a considerable number of selected gem-quality diamonds for birefringence. Two thousand such diamonds were specially selected by their expert sorters, as follows: (*a*) 1,000 crystals (1 carat each), mixed octahedra and dodecahedra; (*b*) 400 flat triangular twins (1 carat each); (*c*) 200 half-carat selected "Cape dies" (dodecahedra), traditionally for drilling, for wire dies, and reputed to be long-lasting in use; (*d*) 400 1 carat fragments (chips).

All 2,000 diamonds were examined, singly, with a simple pocket polariscope consisting of two crossed 'Polaroid' disks and a ×10 eyepiece, the combination fitting over a small hand torch. Without exception, all these gem-quality selected crystals showed some degree of birefringence. There was a wide range in response, but complete extinction was not obtained with any of the diamonds. Twenty crystals (that is, 1 per cent) exhibited a strong localized birefringent region which was clearly linked with a slight local defect or inclusion. About 100 crystals (that is, 5 per cent) were only weakly birefringent, and in most of these the transmitted light appeared in rectilinear patches lying in crystallographic directions. On average, the 200 Cape dies showed less birefringence than did the rest of the diamonds, thus confirming the traditional belief in their strength. Yet many did show several bands of polarization. Notable were the 400 chips, for nearly all showed considerable double refraction, some long chips being the most birefringent of all those examined.

On the basis of these observations made on 3,000 fine-quality micro-diamonds and on 2,000 good-quality gem-stones, it is certainly not rash to conclude that the chances of finding a non-birefringent diamond appear to be remote. There is clearly now a very strong case for believing that almost all diamonds are birefringent. My observations on 5,000 good-quality diamonds confirm the tentative conjecture made by Friedel (in 1924 with his 200 diamonds) that probably all diamonds are birefringent; however, I am quite unable to accept the explanation which he proposed, and I shall offer here an alternative one.

Finding a transition temperature at 1,885° C (ref. 2), where diamond tends to shatter catastrophically, Friedel argued that all diamonds, initially isotropic at formation, pass through a plastic state, sufficient to accept permanent deformation the cause of which is associated with this transition temperature. He went on to argue that this creates the strain leading to the ubiquitous birefringence.

I shall offer quite a different explanation. Harrison and I[3] have sectioned and etched numerous diamonds and have always been able to demonstrate the existence of a stratigraphical etch pattern, often strictly linear, which clearly indicates that diamond must have grown by successive layer formation. Fig. 1 is a typical stratigraphical etch pattern on the surface of a 1-mm slice cut from the mid (girdle) region of a fine-quality transparent octahedron observed by oblique illumination. Bright regions are areas which have accepted heavier etching.

By photographing this slab in light of wave-length just shorter than 3000 Å (which can distinguish type 1 from type 2 diamond) I found that the darker regions of Fig. 1, which are those free from etch (or relatively less etched), are type 2 diamond, while the brighter (heavily etched regions) are of type 1.

Now this diamond like the rest is birefringent; a polariscope picture of the slab is shown in Fig. 2. The slab is highly birefringent and a remarkable correlation is obvious between the etch pattern and the birefringence. To account for this, it is only necessary to postulate that there exists some small difference in either the thermal expansion property or the elastic strength or the lattice dimension of the two distinct types of diamond. Such an assumption would adequately explain the close correlation between the birefringence pattern and the stratigraphy.

To account for the birefringence it is then necessary to propose that all diamonds are layer mixtures of type 1 and type 2 material. Such a conjecture not only explains the universal occurrence of birefringence, but it also accounts for the catastrophic shatter described by Friedel and Ribaud. It explains also the microcharacter of diamond cleavage surfaces. In most diamonds despite the intermixing, one type usually dominates the other, and it is this dominant type which determines the ultimate classification. I have already demonstrated[5]

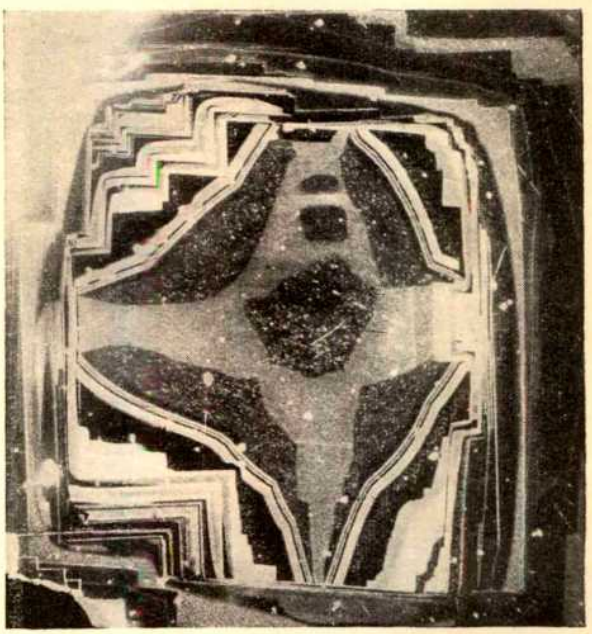

Fig. 1

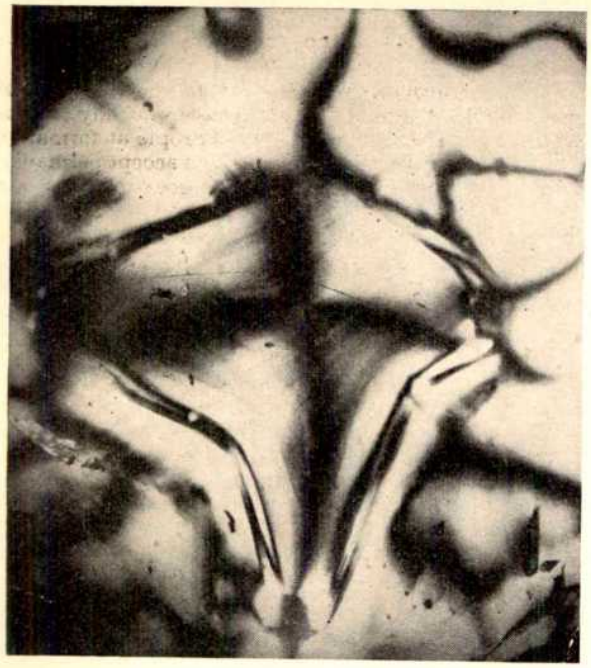

Fig. 2

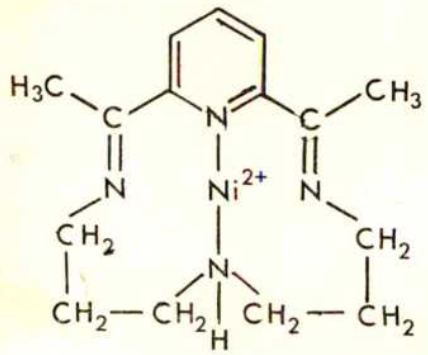
by interferometric studies on cleavage planes that diamonds which are predominantly type 2 cleave much flatter than those which are predominantly type 1. Yet any cleavage usually shows distinct regions, some of which cleave well, mixed with regions which cleave poorly. The conjecture that I make here as to an intermix of types would also explain this aspect of cleavage.

Friedel's idea of a mere mechanical strain is not able to explain why so many of our observed strain patterns follow linear crystallographic directions. On the contrary, because in my view the crystal has grown by way of oriented sheet layers, it is clear that the interfaces between type 1 and type 2 can, in fact, be expected often to orient parallel to crystallographic directions; thus the appearance can be predicted of strain pattern fringes lying along crystallographically oriented directions—and this is found.



Friedel's theory also fails to explain the appearance of strong birefringence in the many chips or fragments. If mere direct mechanical strain were the cause of birefringence in diamond, it could reasonably be anticipated that when such a strained crystal fractured it would tend to do so in such a manner as to tend to relieve the mechanical strain. Thus it would be expected that such strain-relieved fragments would, on the whole, show less birefringence than complete crystals. Yet the contrary is true, which implies that the birefringence is built into the fragments and cannot be released by the act of fracture. In our view, a complete mixing of types would automatically lead to high strain and, if such a strained crystal fractured, the individual pieces, being also complex, would still remain highly strained, as in fact is observed. Thus I noted considerable strain in all the 400 chips which I studied. The strain cannot be relieved by the act of fracture if an intermixing of type 1 and type 2 is responsible for the birefringence as I suggest here.

NICKEL (II) COMPLEXES OF THE TETRADENTATE MACROCYCLE 2,12-DIMETHYL-3,7,11,17-TETRAAZABI*CYCLO* (11.3.1) HEPTADECA-1 (17),2,11,13,15-PENTAENE

By JACK L. KARN and PROF. DARYLE H. BUSCH
Department of Chemistry, Ohio State University, Columbus

As part of the investigation[1,2] of the reaction of linear polyamines with 2,6-diacetylpyridine in the presence of metal ions, Curry prepared the macrocyclic complex cation, 2,12-dimethyl-3,7,11,17-tetraazabi*cyclo* (11.3.1) heptadeca-1 (17),2,11,13,15 pentaene-nickel (II), hereafter referred to as NiL^{2+} (Structure I).

(I)

The perchlorate salt was characterized by its infra-red spectrum, elemental analyses (carbon, hydrogen, nitrogen and chlorine), and determination of the formula weight in water using a 'Mechrolab' Osmometer (calculated for monomer, 516; found, 518). Rich and Stucky[3] claimed to have isolated the tetrachlorozincate salt of this cation but have offered spectral data for a product that has not been analysed. They have identified the copper complex as the tetrachlorozincate.

The complex ion of structure I, NiL^{2+}, is planar with unhindered axial sites, so that salts containing anions or other donors, such as water, provide a series of tetragonal complexes in which the nickel ion is subjected to a relatively constant in-plane ligand field but varying axial perturbation. Some of the chemical and physical properties of a number of these complexes have been examined in the course of a general investigation of tetragonal macrocyclic nickel (II) complexes.

Syntheses

$NiL(ClO_4)_2$ was prepared as described by Curry[1] by the reaction of stoichiometric quantities of $NiCl_2 \cdot 6H_2O$, diacetylpyridine, and diaminodipropylamine in 50 : 50 water-ethanol solution for several hours at 60° C. After

the removal of the bulk of the ethanol by evaporation, the crude product was precipitated by the addition of concentrated aqueous sodium perchlorate. The product was recrystallized from warm water, yielding grey-brown needles which turn brick red on removal of co-ordinated water *in vacuo*. The dihydrate of the perchlorate salt was prepared by letting the anhydrous salt stand in a water-saturated atmosphere.

The chloride and thiocyanate salts were prepared by the addition of lithium chloride or sodium thiocyanate to an acetone solution of the perchlorate salt, the chloride or thiocyanate immediately precipitating. These products were recrystallized from chloroform. Both these products precipitate as anhydrous salts, but the chloride readily picks up water to form the hydrate, turning from olive green to grey. The brown thiocyanate shows no tendency to pick up water.

Ni*L*Br$_2$·H$_2$O was precipitated by the addition of a concentrated solution of sodium bromide to aqueous Ni*L*Cl$_2$. The product was recrystallized from warm water. The addition of concentrated sodium bromide solution to aqueous solutions of Ni*L*(ClO$_4$)$_2$ or Ni*L*(BF$_4$)$_2$ results in the precipitation of the mixed salts Ni*L*Br(BF$_4$)·H$_2$O or Ni*L*Br(ClO$_4$)·H$_2$O.

The analytical data are reported in Table 1.

Magnetic and Spectral Properties

The magnetic susceptibilities of the samples were determined from room temperature to liquid nitrogen temperatures by the Gouy method. Ni*L*(ClO$_4$)$_2$ and Ni*L*ZnCl$_4$ (ref. 3) are diamagnetic, and are presumed to be square planar complexes. The infra-red spectrum of the perchlorate salt shows no evidence of co-ordination by the perchlorate anions. Ni*L*Cl$_2$, Ni*L*(SCN)$_2$, and Ni*L*(H$_2$O)$_2$(ClO$_4$)$_2$ are paramagnetic species which exhibit normal Curie-Weiss temperature dependence. The Curie-Weiss plots for these complexes are shown in Fig. 1, where the curves are constructed from a least squares fitting of the depicted data points.

Ni*L*Br$_2$·H$_2$O is diamagnetic. This is interesting in view of the fact that similar macrocyclic complexes of nickel, such as the bromide salt of the hexamethyltetraaza*cyclo*-tetradecane complex reported by Curtis[4], are paramagnetic. Since stereomodels indicate that the axial sites in Ni*L*$^{2+}$ are considerably less hindered than in the Curtis macrocycle, the failure of bromide to produce a paramagnetic complex cannot be attributed to steric factors. It may be that, as a result of the stronger field produced by the azo-methine groups in Ni*L*$^{2+}$, the weak axial perturbation produced by the bromide ion is insufficient to unpair the electrons of the nickel(II) ion. It seems quite unlikely, however, that Ni*L*Br$_2$·H$_2$O is a 6-co-ordinate species with both bromides co-ordinated, since the complex shows no solubility in chloroform in which Ni*L*Cl$_2$, Ni*L*(SCN)$_2$, and the tetragonal chloride and bromide salts

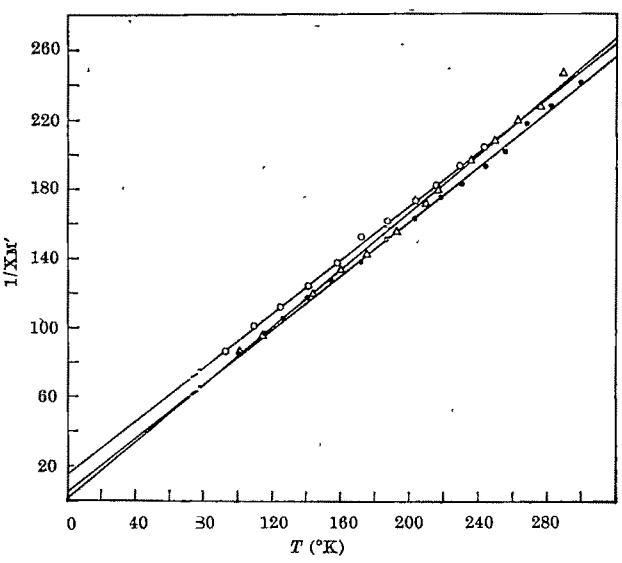

Fig. 1. Temperature dependence of susceptibility of tetragonal complexes of 2,12-dimethyl-3,7,11,17-tetraazabi*cyclo* (11 3.1) heptadeca-1 (17),2,11,13,15-pentaene ○, Ni*L*(H$_2$O)$_2$(ClO$_4$)$_2$, μeff = 3·22 B M., θ = 19·1°; △, Ni*L*(SCN)$_2$, μeff = 3·11 B.M., θ = 0·3°, ●, Ni*L*Cl$_2$, μeff = 3·22 B M., θ = 6·9°

of the Curtis macrocycle are soluble. It is also difficult to explain the intense colour of this complex if 6-co-ordination is assumed.

A particularly striking observation is that the visible absorption spectrum of Ni*L*Br$_2$·H$_2$O is virtually identical to that of the mixed salts Ni*L*Br(BF$_4$)·H$_2$O and Ni*L*Br(ClO$_4$)H$_2$O and markedly different from that of the planar Ni*L*(ClO$_4$)$_2$ complex or the tetragonal Ni*LX*$_2$ (where *X* is chloride, thiocyanide or water) complexes. Examples of these spectra, which were run on Nujol mulls using a 'Cary 14' spectrophotometer, are given in Fig. 2, and the band maxima are tabulated in Table 2.

The possibility that water is co-ordinated at one axial site in these complexes with bromide at the opposite position is rather remote, since the average field thus produced should be at least as strong as that resulting from the axial co-ordination of chloride, which produces a paramagnetic complex. Although the possibility of 6-co-ordinate bridged bromide complexes cannot definitely be ruled out for Ni*L*Br$_2$·H$_2$O, Ni*L*Br(BF$_4$)·H$_2$O, and Ni*L*Br(ClO$_4$)·H$_2$O, the objection to such structures on the basis of the deep colour of these complexes can again be raised. The co-ordination number of five seems highly likely for these substances.

The part played by water in these complexes is almost certainly a significant one. Ni*L*Br$_2$·H$_2$O and the two mixed salts contain 1 mole of water which is not removed by heating to 109° C *in vacuo*. The infra-red spectra of

these complexes show sharply split bands in the region of the O—H stretching frequency, and it seems likely that the molecule of water exerts a profound effect on the structure of the complex. A number of examples of the interaction of water with co-ordinating anions have been observed previously. The anhydrous chloride and bromide salts of the Curtis macrocycle are paramagnetic, while their dihydrates are diamagnetic[4]. Since the spectrochemical series would lead one to expect, if anything, the reverse behaviour, it must be assumed that water is interacting with the halides in some manner which either prevents their co-ordinating or weakens their donor strength. Similarly, Melson and Busch have found that the bromide and chloride salts of the complex ion tetrabenzo-[*b*, *f*, *j*, *n*] [1, 5, 9, 13] tetraaza*cyclo*hexadecine-nickel(II) contain one mole of water, which can only be removed with difficulty, and have postulated that hydrogen bonding between this water molecule and the halides is responsible for lowering the ligand field of the halides and producing the abnormally low magnetic moments observed for these complexes[5].

A particularly interesting hydrate structure has been proposed by Goodgame and Venanzi to explain the fact that the dihydrate of *bis*(*N*,*N*-diethylethylenediamine) nickel(II) bromide is paramagnetic whereas the anhydrous compound is diamagnetic[6]. In this case Goodgame and Venanzi suggest that hydrogen bonding as shown in Structure II is responsible for holding the bromide ions in the axial sites.

(II)

A similar interaction of water with the bromide in Ni*L*Br$_2$ and the mixed salts, which have only one N—H bond, would produce essentially 5-co-ordinate, diamagnetic complexes. The choice of this structure (III) is a compelling one, since it accounts for the tendency of the complex to bind only one molecule of water and for the splitting of the O—H band in the infra-red spectrum.

(III)

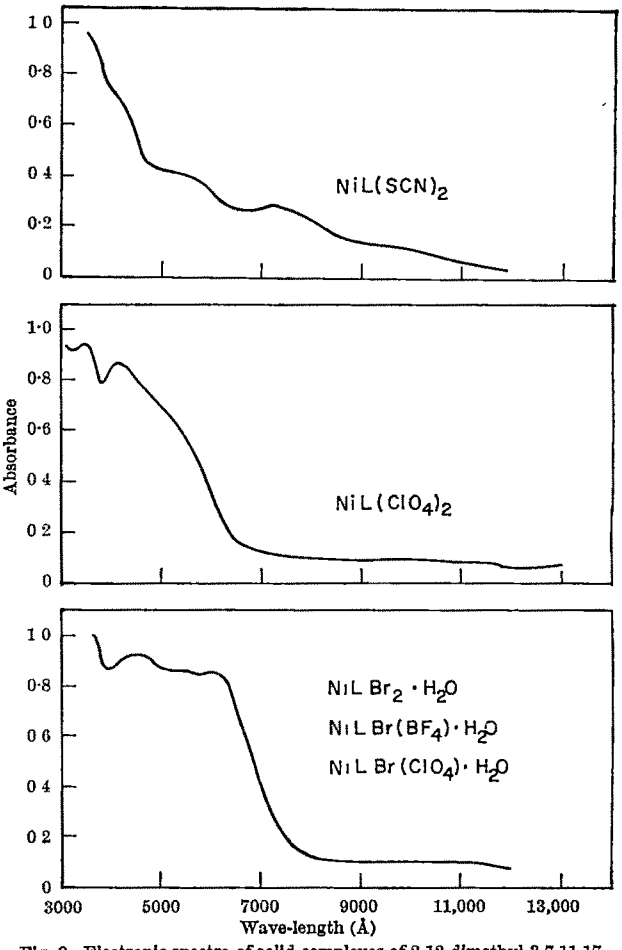

Fig. 2. Electronic spectra of solid complexes of 2,12-dimethyl-3,7,11,17-tetraazabi*cyclo* (11.3.1) heptadeca-1 (17),2,11,13,15-pentaene

The intense colour of the complexes, which exist as fine black needles, is consistent with this low degree of symmetry. The molar conductance of Ni*L*BrBF$_4$·H$_2$O in CH_3NO_2 is 84·1 ohm^{-1} at 21°, as expected for a uni-univalent electrolyte[7].

Reduction of the Azo-methine Linkages

The catalytic reduction of the azo-methine linkages in this macrocycle yields two isomeric products which are red and yellow in colour. with the red form predominating. The infra-red spectra of the products show enhancement of the N—H band at 3,180 cm^{-1} and diminution of a band at 1,570 cm^{-1}, presumably the C=N band in the starting material. The complete disappearance of this band is not observed because it coincides with a band originating from the diacetyl-pyridine moiety. Hydrogen uptake is consistent with that expected for the reduction of both azo-methine linkages. It can be concluded that these two isomeric forms are geometric isomers with the two methyl groups extending on either the same or opposite sides of the plane of the nickel ion (meso and racemic, respectively). Further results on the reduced complexes and its salts will be reported elsewhere.

This investigation was supported by a grant from the U.S. Public Health Service from the National Institute of General Medical Sciences.

AT daybreak on January 24, 1966, ash-charged vapour columns were seen over Mt. Redoubt from Kenai and Anchorage, Alaska. Reports soon confirmed that the column was being erupted through a new fissure vent on the north ridge of the volcano below the old crater. Mt. Redoubt (3,110 m) is located at 152° 50′ W. long., 60° 30′ N. lat., 550 km from College, Alaska, at an azimuth of 210°. The volcano has been active during at least five previous occasions in historical time as summarized in Table 1.

Table 1. MT. REDOUBT VOLCANO

Year	Type of activity
1778	Active (type unknown)
1819	Smoke (steam and/or ash clouds)
1902	Active (type unknown)
1933	Smoke (steam and/or ash clouds)
1965	Sporadic emission of vapour plumes (from a new fissure on north flank)

The chronology of the recent eruptive cycle is:

January 24, 1966. A turbulent ash-charged cloud which reached an altitude of 6,100 m was reported over the volcano; the presence of a new vent at the 2,300-m level on Redoubt was reported by aircraft in the area.

January 25–27, 1966. Heavy cloud cover obscured the volcano; however, on January 25 an eruptive cloud appeared above the cloud deck. Its height was estimated at 12,000 m by a jet pilot flying near Redoubt.

January 28, 1966. Helicopter reconnaissance by one of us revealed that activity had decreased to the rather steady emission of a turbulent but ash-free steam cloud.

February 5, 1966. A second eruptive cycle of ash-charged gas columns began after a quiescent period of 9 days.

February 6–8, 1966. Visual observations were hampered by bad weather conditions, but reports on February 8 indicate the emission of a persistent 4,570–6,100 m ash-charged vapour column throughout the day.

February 9–10, 1966. Another day of marginal visibility; two columns were erupted which were closely monitored by U.S. Air Force radar facilities and aircraft at Kenai, Alaska. Shortly after 1900 h U.T., a U.S. Air Force plane reported the emergence of a brown-coloured turbulent cloud which mushroomed at 13,720 m from a closed deck below. This elevation was confirmed by U.S. Air Force radar control at Kenai. On February 10, at 0050 h U.T., the radar station at Kenai reported another eruption cloud which mushroomed at 9,700 m.

February 20, 1966. Activity was markedly reduced from February 10 until February 20 when a Geophysical Institute seismic research team on the south ridge of Mt. Redoubt reported a steam and ash cloud at 1938 h U.T. which rose to 5,000 m. There has been no further activity other than the emission of a continuous column of steam similar to the activity which characterized the two interim quiescent periods.

So far, lava has not been erupted from the new vent and no crater development has been observed. The ejecta deposited by the eruptive clouds are composed of andesite pumice, scoria and lithic fragments, and a sand-sized fraction consisting of discrete and fractured grains of quartz, feldspar and hornblende, which has apparently been derived from granitic sub-volcanic basement rocks. Glass shards are rare or absent in ejecta deposited up to 1 km from the vent and the lithic and erupted fragments show no evidence of magmatic transport.

The explosive clouds erupted by Mt. Redoubt were apparently derived from the rapid degassing of an andesitic magma which was initiated at considerable depth. The lithic fragments were probably derived from the attrition of andesite flows within the volcanic pile, but the pumice and scoria are believed to represent the vesiculated and degassed equivalent of the juvenile magma.

During the period of January 24–February 20, 1966, infrasonic pressure waves travelling at acoustic velocities were observed at the Geophysical Institute at College, Alaska, following the eruptions of Mt. Redoubt. The infrasonic signals were detected by a quadrilateral array of microphone stations using equipment and techniques developed by the National Bureau of Standards[1]. Assuming a plane wave solution, one can determine the azimuth of the arriving signal as well as the horizontal trace velocity V_h of the waves from the arrival times of the pressure waves at the four microphones. If the angle between the wave normal and the horizontal plane is α, then α is given by $V_h = V_\varphi \sec \alpha$, where V_φ is the local velocity of sound. From the analogue recording of the pressure variations as a function of time one can obtain the absolute amplitudes, the periods and dispersion of the infrasonic waves. The acoustic waves from the Mt. Redoubt eruptions were recorded without filtering on magnetic tape and also on charts with two different bandpass filters, namely, an $N7$ channel filter with half-amplitude points at 9 sec and 70 sec, and an $N6$ channel bandpass from 0·1 sec to 35 sec.

Six separate infrasonic events were associated with the various eruptions of Mt. Redoubt. Each of these events can be related to the eruption of a specific turbulent cloud. The strength of the infrasonic signals was generally proportional to the height of the erupted cloud. From the observed character of the eruptions the infrasonic pressure waves were probably generated by the sudden ejection of large volumes of high-pressure gas by the volcano rather than by explosions of the type reported by Gorshkov[2] and Goerke *et al.*[3] for Bezymianny and Agung volcanoes.

The characteristics of these six infrasonic events are given in Table 2 together with the height of the erupted cloud in metres and the component of the wind in m/sec at the 30-km level from an azimuth of 210°. The average azimuth of all the infrasonic signals from Redoubt was 210·8° with seldom more than ±5° variation from this direction. The various waveforms of the infrasonic pressure waves are shown for events numbers 1, 2, 4 and 6 in Fig. 1 in which the waves have been superimposed to give the best correlation of phase of the pressure waves among the four microphone sites.

Table 2 shows that for all events, with the exception of number 3 in which the signal was only a single pressure

Table 2. MT. REDOUBT INFRASONIC SIGNALS

spike, there were two arrivals of infrasonic energy associated with each volcanic eruption. The two successive arrivals of infrasonic energy can best be seen in Fig. 1 for the events on January 24 and February 20. The first arrivals are at 1000 h and 2003 h, while the second are at 1012 h and 2010 h on January 24 and February 20, respectively. A difference in the alignment of the superimposed pressure records between the first and second signals is indicated by the break in the time line. The sequences of numbers 1, 2, 4, 3 on the time line in Fig. 1 give the time of arrival sequence of the waves at the four microphone sites. The difference in the character of the incoherent noise and the presence of an infrasonic signal can be clearly seen in Fig. 1 for the January 25 event. The four pressure traces exhibit random fluctuations from the beginning of this record until 2130 h when the coherent signal arrived and all four traces became superimposed.

The average delay time between the two infrasonic signals is 10 min for the five events. The trace velocity is greater for the second signal than for the first in all these events. The averaged velocities are $V_h = 343$ m/sec for the first wave and $V_h = 426$ m/sec for the second. If the local acoustic velocity is given by $C = 20{\cdot}60\sqrt{T}$ m/sec, where T is the absolute temperature, then for the temperature measured by balloons at the 7-km level of 230° K, we find that $C = 304$ m/sec. Using this velocity as an approximation of the group velocity of the infrasonic waves, the travel time to cover the 550 km distance by a level path would be about 30 min. Thus, a 10-min delay time for the second signal indicates that the path for the second signal was about 30 per cent longer than that for the first signal. If V_φ is assumed to be 304 m/sec, then the angle of incidence of the first wave is about 28° while that of the second is about 45°. From these considerations we conclude that the infrasonic pressure waves are travelling from Mt. Redoubt to the observing site by two different acoustic channels in the atmosphere. The signal which arrives first travels in the lower sound channel, described by Diamond[4], between the ground and the 50-km level. The second signal which arrives from a larger angle of incidence travels in the higher channel, described by Pfeffer and Zarichny[5], from the 50-km to the 110-km level.

The normal dispersion (that is, group velocity increasing with increasing period) of the wave trains of the first signal in events numbers 2 and 4, which can clearly be seen in Fig. 1, is consistent with the dispersion expected for acoustic propagation by the fundamental mode in the first sound channel[5]. Further evidence of the normal dispersion of the ducted infrasonic waves can be found by averaging the trace velocities in Table 2 for the high-frequency $N6$ and lower-frequency $N7$ bandpass filters. The average velocity for the "first signal" which propagated in the lower sound channel for the $N6$ bandpass is 342 m/sec while that for the $N7$ bandpass is 359 m/sec. Thus a higher group velocity, characteristic of normal dispersion for the longer period waves in the lower sound channel, is indicated by the higher average trace velocity for the signals observed on the $N7$ relative to the $N6$ bandpass filters. Superposition of the second signal on the tail of the first makes it impossible to determine the dispersion characteristics of the second signal.

No evidence was found of infrasonic waves that had propagated around the Earth by a great circle path through the Antipodes from any of the Mt. Redoubt eruptions as were observed in the case of the eruptions of Mt. Agung[3]. The lack of such east-to-west propagation of acoustic signals is consistent with the inhibiting effect of the westerly winds on the lower sound channel in winter[4].

The effect of the wind on the strength of the received signals may account in part for the difference in the amplitude and duration of the infrasonic waves. The amplitude of event number 2 was much greater than that of number 4. Although the heights of the erupted clouds were about the same for these two events, the wind at the 30-km level, as shown in Table 2, would favour the development of a strongly ducting sound channel[4] for event 2 while inhibiting it in event 4.

The difference in the observed periods of the pressure waves for these two events can be used to show that event number 2 was intrinsically more energetic than number 4

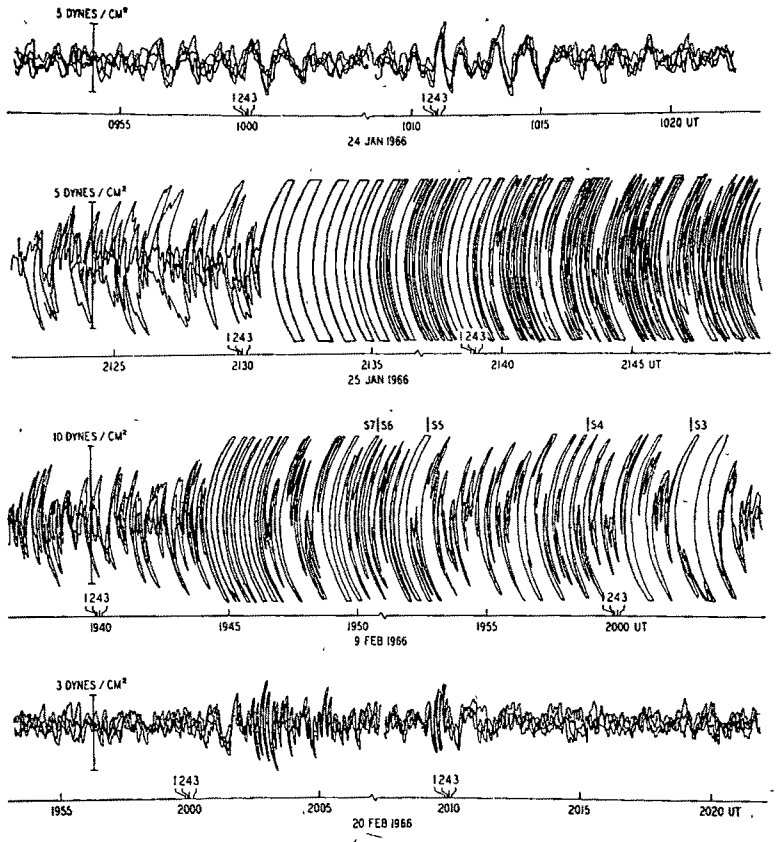

Fig 1. Infrasonic waves from Mt. Redoubt

even though some of the differences in their amplitudes can be explained by wind effects. Hunt *et al.*[6] have shown that the average period of the largest wave due to an explosion in the atmosphere is roughly proportional to the cube root of the energy released by the explosion. The mean periods of the waves in events 2 and 4 averaged over the first four cycles are 55 sec and 21 sec, respectively. The ratio of the infrasonic energy released in event 2 to that in 4 would then be $(T_2/T_4)^3$ or about 18 to 1. Unfortunately the bad weather conditions on January 25 prevented this being verified by visual observations.

It is possible to estimate from the amplitude of the pressure waves the volume of gas ejected by the volcano by use of a model developed by Hunt *et al.*[6]. They calculate the pressure variations as a function of time and distance from a source which injects 1 km³ of gas into the atmosphere. By extrapolation of their curves in Fig. 7*a* for the pressure variations at a distance of 1,000 km from the explosion site to the closer distance of 550 km (the Redoubt to College distance) it was found that the injection of 1 km³ of gas at the explosion site would cause a 30-dynes/cm² pressure wave at a distance of 550 km from the explosion. The volume of gas ejected by the Redoubt eruptions which generated the infrasonic pressure waves can be found by calculating the ratio of the observed pressure variation at College to the extrapolated theoretical variation of 30 dynes/cm² and multiplying this by 1 km³.

The maximum amplitude of the February 9 infrasonic pressure wave from the magnetic tape record was 16 dynes/cm². This gives a volume of gas injected into the atmosphere by the eruption of about 0·5 km³. Because the signal from the January 25 eruption was off-scale on the chart recorders and had saturated the magnetic tape record, we can only estimate the volume of gas ejected by Mt. Redoubt for this event as eighteen times that of the event of February 9, or 9 km³. This follows from our previous discussion of the relative energy of the events of February 9 and January 25 which we derived from the ratio of the periods of the two infrasonic waves.

The energy of the eruptions which ejected the gas clouds from the fissure vent on Mt. Redoubt can be found by calculating the work done by the ejected gas in expanding against the ambient atmospheric pressure at the level of the vent. The energy is thus given by $\int_0^V P\mathrm{d}v$ where V is the volume of the ejected gas and P is the constant pressure at the 2300-m level or $0{\cdot}8 \times 10^6$ dynes/cm². The energy necessary to inject 0·5 km³ of gas in the February 9 eruption is thus $(0{\cdot}8 \times 10^6$ dynes/cm²) $(0{\cdot}5 \times 10^{15}$ cm³) or 4×10^{20} ergs. For the January 25 eruption the energy would be about 7×10^{21} ergs.

Our findings can be compared with those of G. S. Gorshkov[2] in his study of the explosion of Bezymianny volcano, Kamachatka, U.S.S.R., on March 30, 1959. Using microbarograph data from eight meteorological stations at distances from 45 km to 760 km from the volcano, Gorshkov calculated an average value of 3×10^{22} ergs for the air wave generated by the explosion. Gorshkov stated that about 10 per cent of the total energy of the volcanic explosion was transformed into resultant air wave energy. Thus Gorshkov estimated the total energy of the Bezymianny eruption to be approximately 3×10^{23} ergs.

In the case of Mt. Redoubt, because of the non-explosive character of the eruptions, the fraction of the total energy of the eruption which was consumed as work necessary to eject the gas clouds against atmospheric pressure is thought to represent the majority of the energy of the eruption. Some energy would be used in imparting kinetic energy to the solid ejecta; perhaps one-third of the total energy. Thus we can establish lower limits for the energies of the Mt. Redoubt eruptions as 6×10^{20} ergs for the event of February 9 and $1{\cdot}05 \times 10^{22}$ ergs for that of January 25.

We thank Mr. William J. Best, chief of the Geophysics Division, Air Force Office of Scientific Research, for the authorization and co-ordination of the direct air support provided by the 5017th Operational Squadron and the logistics and technical aid given by the Air Force staff and operational units at Elmendorf Air Force Base, Alaska. The geochemical and infrasonic studies of Mt. Redoubt were also supported in part by the National Science Foundation and the U.S. Department of Commerce, E.S.S.A.

PRODUCTION OF MESONS IN THE NUCLEI OF GALAXIES

By DR. D. F. FALLA
Department of Physics, University College of Wales, Aberystwyth

THE emission of radiation by electrons from the decay of mesons produced in high-energy astrophysical processes has frequently been discussed. Some years ago, Burbidge[1] and Ginsburg[2] considered π meson production in the interaction of fast cosmic ray protons with galactic material; while Burbidge and Hoyle[3] considered π meson production in the annihilation of anti-nucleons. The electrons from the meson decay reactions:

$$\pi \rightarrow \mu + \bar{\nu} \text{ and } \mu \rightarrow e + \nu + \bar{\nu} \qquad (1)$$

could then, under favourable conditions of electron energy and galactic magnetic field, produce synchrotron radiation in the optical and radiofrequency regions of the spectrum. Burbidge and Hoyle found that it was possible, on the basis of their proposed model, to meet the luminosity requirements of the most energetic radio sources, provided that the number of anti-nucleons in the galaxy could be maintained at a constant level—a level which would, moreover, be consistent with the pair production of nucleons at a rate given by the requirements of steady-state cosmology.

In these models, no assumptions had to be made regarding any possible localization of the meson production process within the galaxy.

Later, Burbidge, Burbidge and Sandage[4] presented detailed evidence for the occurrence of violent events in the nuclei of galaxies, including the Seyfert galaxies and a number of the strong radio sources, and suggested that the nuclei may have many effects on the structure and evolution of these galaxies and may be the ultimate sources of their energy. Hoyle and Fowler[5,6] at the same

time proposed a model on which an energy sufficiently large to account for the strong radio sources could be produced by a galactic nucleus, in the form of a massive star, as a result of its gravitational contraction.

Following the discovery of the quasi-stellar radio sources[7,8], several further models were advanced to account for the existence of highly localized sources of great energy: Fowler[9,10] developed the massive star model, and a similar system was discussed by Greenstein and Schmidt[11]; while Field[12], Woltjer[13] and Gold *et al.*[14] considered various processes which could occur if the galactic nucleus were to consist of a stellar cluster rather than a single star.

I shall propose here a model which has features in common with several of those already suggested. We consider a process whereby new material is accreted from intergalactic space by a galactic nucleus consisting of hydrogen already at an advanced stage of condensation; and we shall now investigate the situation for which this material, before its entry into the galactic nucleus, has acquired an energy exceeding the threshold for the production of π mesons and anti-nucleons. Adopting a phrase originally applied by Salpeter[15] to the accretion of interstellar matter by a massive star, this process can be described as one of "catastrophic accretion". I suggest that such a process, centred on a galactic nucleus of radius somewhat greater than its Schwarzschild limit, could lead to the production of π mesons and anti-nucleons: decay of the π mesons would give rise to fast electrons as already discussed, while the anti-nucleons would give the same ultimate decay products, but by way of the production of π mesons in the process of annihilation

For a proton or hydrogen atom, henceforth referred to simply as a proton, entering the gravitational field of the galaxy from a distance which is large by comparison with the radius (R) of the nucleus, the appropriate equation of motion gives the final velocity (βc):

$$(\beta c)^2 = \frac{2MG}{R} = \frac{8\pi}{3} G (R^2 \rho) \qquad (2)$$

where M and ρ are the mass and density of the galactic nucleus, and G the constant of gravitation. (R is the Schwarzschild radius for the mass M at $\beta = 1$.)

The production of π mesons and anti-nucleons may occur in initial interactions of the types:

$$p + p \rightarrow N + N + n\pi \qquad (3a)$$

and

$$p + p \rightarrow N + N + N + \overline{N}: \qquad (3b)$$

In the first the proton energy threshold for the production of a single π meson ($n = 1$) is 300 MeV, while in the second the threshold for the production of an anti-nucleon is 5·6 GeV. We calculate from equation (2) the values of $R^2\rho$ required for the attainment of the corresponding values of β : $R^2\rho$ equals $0{\cdot}685 \times 10^{27}$ g cm^{-1} for equation (3*a*), and $1{\cdot}575 \times 10^{27}$ g cm^{-1} for equation (3*b*).

We consider proton–proton interactions at an arbitrary energy of 7 GeV, for which $R^2\rho$ has a value very similar to the second of these figures, and for which many data have been collected from experiments with the *Nimrod* and *Bevatron* proton synchrotrons. From this required value of $R^2\rho$ we calculate ρ and also M, expressed in solar mass units, for different values of R. Some of the results are given in Table 1.

A galactic nucleus specified by one of the sets of figures given in Table 1 could act as a 7-GeV cosmic proton accelerator, and give rise to the production of π mesons

Table 1. PARAMETERS DESCRIBING GALACTIC NUCLEUS

R (cm)	ρ (g cm^{-3})	$\frac{M}{M\odot}$
10^{14}	$1{\cdot}6 \times 10^{-1}$	$3{\cdot}3 \times 10^{6}$
10^{15}	$1{\cdot}6 \times 10^{-3}$	$3{\cdot}3 \times 10^{9}$
10^{16}	$1{\cdot}6 \times 10^{-5}$	$3{\cdot}3 \times 10^{12}$

and anti-nucleons in the process of catastrophic accretion occurring at this energy.

It is essential, however, that the charged π mesons should have a large probability of free decay, eventually to electrons, and only a small probability of secondary interaction. This condition immediately sets an upper limit to the density of the hydrogen of the galactic nucleus. We estimate from the results of calculations by Morgan[16] that an approximate mean momentum for π mesons produced by 7 GeV protons is 1 GeV/c. In general, the mean free path for meson decay at a momentum of p is given by:

$$\lambda\,(\text{decay}) = \tau c\beta\gamma = \tau\left(\frac{p}{m_0 c^2}\right)$$

where τ is the proper lifetime of the meson. Now it is the lifetime of the π meson which is relevant here, because only the strong interactions of the π mesons offer competition to the production of decay electrons, even though the μ meson has the longer lifetime. Taking, therefore, a value of τ equal to $2{\cdot}55 \times 10^{-8}$ sec, we find that λ (π decay) $= 5{\cdot}45 \times 10^{3}$ cm. For the interaction of charged π mesons in hydrogen we estimate, from data summarized by Kallén[17], that the total cross-section at 1 GeV/c is 38 millibarns: the mean free path for interaction is then given by $\lambda(\pi$ interaction$) = (N\rho\sigma)^{-1}$ $= (0{\cdot}023\ \rho)^{-1}$. In order that, for the π mesons, decay should be more probable than interaction, $(0{\cdot}023\,\rho)^{-1} \geqslant 5{\cdot}45 \times 10^{3}$, which sets an upper limit to ρ equal to $0{\cdot}8 \times 10^{-2}$ g cm^{-3}. This corresponds to a lower limit for R of $4{\cdot}45 \times 10^{14}$ cm.

The range of possible values of R is also limited by the mass of the galactic nucleus. If we take as a guide the figures for the dimensions and mean density of our own Galaxy[18], we find that unless $R \lesssim 3 \times 10^{16}$ cm the whole of the galaxy mass is concentrated in the nucleus; and if we consider only galactic systems similar in total mass to our own, this value of R may be taken as an upper limit to the radius of the galactic nucleus on our model.

With regard to these limits, we conclude that an acceptable value for R would be 10^{15} cm, with values for ρ and M as given by Table 1, although it could be as high as 10^{16} cm if an appreciable fraction of the galaxy mass were concentrated in the nucleus. The former figure is taken in most of the subsequent calculations.

For a catastrophic accretion process centred on a galactic nucleus described by these figures, the interaction mean free path for the incident protons, initially in the tenuous material of the envelope and then in the denser material of the nucleus, may be estimated approximately in terms of the proton–proton cross-sections and the appropriate densities of the material. A survey of the values taken by the cross-section over the energy range corresponding to the difference in radii of the galactic envelope and the galactic nucleus suggests that at no stage is the proton acceleration process inhibited appreciably as a result of proton interaction with the material of the envelope: for a mean density of galactic material[18] of 7×10^{-24} g cm^{-3}, a proton can easily derive enough energy from the gravitational field over a distance of an interaction mean free path to more than compensate for any energy loss by collision. For the galactic nucleus, we may take for the inelastic cross-section the particular value of 27 mbarns[19] which, for the value of ρ already estimated, corresponds to a mean free path of $3{\cdot}9 \times 10^{4}$ cm. It can therefore be concluded that the protons incident on a galaxy described by our model reach the centre without an appreciable loss of energy, and that their interactions are localized in the extreme periphery of the nucleus.

We now estimate the rate of production of energy in the form of fast electrons inside the galactic nucleus. First, we calculate the flux of protons, dN/dt, gravitating from the region of intergalactic space, at a distance $\mathfrak{R}$

from the galactic centre, where the density of protons is ρ_0 cm^{-3}:

$$\frac{dN}{dt} = \left(\frac{64}{3\pi}\right) MG\rho_0 T \text{ protons sec}^{-1} \quad (4)$$

where T is the accretion time for protons from this region, and which is related to $\mathfrak{R}$ by the expression:

$$T = \pi\left(\frac{\mathfrak{R}^3}{8MG}\right)^{\frac{1}{2}} \text{ sec} \quad (5)$$

If we take for $\mathfrak{R}$ a distance equal to half the mean separation between galaxies in a cluster of typical size, and set the maximum energy attained by the protons equal to our arbitrary energy of 7 GeV, so that M has the value already estimated, we find that:

$$\frac{dN}{dt} = 3{\cdot}92 \times 10^{54}\rho_0 \text{ protons sec}^{-1} \quad (6)$$

The corresponding value of T is $1{\cdot}31 \times 10^{18}$ sec, which is of the order of the Hubble time. Only a comparatively brief phase towards the end of this total accretion time is, however, relevant to the occurrence of the high-energy processes at present being considered on our model.

Secondly, we estimate the mean energy produced, in the form of fast electrons, per incident proton. We assume that the whole of the inelastic cross-section of 27 mbarns[19] represents direct π meson production in proton interactions of the type (3*a*). The meson multiplicity n measured at this energy, the π meson charge ratio deduced from charge independence, and a small correction for the finite probability of π meson secondary interaction together give the result that the mean number of decaying charged π mesons is 1·2 per incident proton. We estimate that for a π meson momentum of 1 GeV/*c* about 4 per cent of the meson decay energy appears in the form of fast electrons, and we finally obtain the figure of $7{\cdot}6 \times 10^{-5}$ ergs for the mean electron energy produced per incident proton.

To see if the catastrophic accretion process could give a rate of energy production comparable with that observed for the quasi-stellar sources, we shall leave aside for the moment any consideration of the other products of the incident proton interaction, and try to explain the energy production in terms of electron energy alone. Combining the figures obtained for incident proton flux and electron energy produced per proton, and leaving ρ_0, the density of protons in intergalactic space, as an undetermined parameter, we put the product equal to the total luminosity of a quasi-stellar source, taking for example the figure of 10^{46} ergs sec^{-1} for the source 3*C* 273 derived from the estimate made by Greenstein and Schmidt[11]:

$$(3{\cdot}9 \times 10^{54}) \times (7{\cdot}6 \times 10^{-5})\ \rho_0 = 10^{46} \quad (7)$$

which has the solution $\rho_0 = 3{\cdot}4 \times 10^{-5}$ cm^{-3}. If we had taken R as 10^{16} cm, the right-hand side of equation (6) would have been $(1{\cdot}24 \times 10^{55})\ \rho_0$ protons sec^{-1}, which would have given $\rho_0 = 1{\cdot}1 \times 10^{-5}$ cm^{-3}. These values of ρ_0 correspond to hydrogen densities in intergalactic space of $5{\cdot}7 \times 10^{-29}$ g cm^{-3} and $1{\cdot}8 \times 10^{-29}$ g cm^{-3} for $R = 10^{15}$ cm and $R = 10^{16}$ cm, respectively.

These figures are very similar to the theoretical values discussed by various authors: Sciama[20], for example, suggests that matter exists in intergalactic space with a density of 2×10^{-29} g cm^{-3}. An upper limit to the density of neutral hydrogen in intergalactic space, derived from the results of observations at a frequency of 21 cm discussed by Davies[21], is $4{\cdot}3 \times 10^{-29}$ g cm^{-3}. On our catastrophic accretion model, the density is the total density of intergalactic hydrogen, both neutral and ionized, so that our figures are consistent with this upper limit for a wide range of levels of ionization, each level corresponding to a different temperature for the intergalactic hydrogen. Sciama[20] has, however, pointed out that if the temperature of the intergalactic gas exceeds 10^5 °K, the gas is thermally stable against collapse. As we may expect a similar condition to apply to our model, it is clear that the model may be feasible only if the temperature is, in fact, less than this limiting value.

Recently reported[20] observations by Gunn of the Lyman-α radiation from the quasi-stellar source 3*C* 9 have suggested that the density of intergalactic neutral hydrogen may be as low as 5×10^{-35} g cm^{-3}. If this result is confirmed, then we may have to revise our conclusions in one of two ways: either we may take this figure to be an indication of a very high level of ionization, in the event of which our model in its present form may no longer be feasible for the correspondingly high gas temperature; or we may take the figure to be an indication of a very low total gas density, in which case our model is still feasible but gives a lower rate of energy production. For the second alternative, an improved situation would result if the "local" density of the intergalactic gas within a galactic cluster were several orders of magnitude higher than that outside: the rate of energy production could then be as large as previously estimated.

Whether a given intergalactic hydrogen atom is neutral or ionized would seem to matter most when it enters the envelope of the galaxy. At this stage of the accretion process, the kinetic energy is already greater than the ionization energy for hydrogen, so that ionization of a neutral atom occurs when it interacts with the material of the outer envelope. Any free electrons produced in this process can be expected to diffuse inwards, but to an extent which is significantly affected by local values of the galactic magnetic field.

In considering energy production in the nucleus of the galaxy we have only, so far, dealt with the contribution made by fast electrons from charged meson decay, and have assumed that these electrons when injected into the magnetic field of the nucleus can produce observable synchrotron radiation. Our conclusions would be modified, in favour of our obtaining a more powerful energy source for a given intergalactic gas density, if other products of high-energy proton interactions of the types indicated in equation (3) were also taken into consideration. We estimate that whereas less than 1 per cent of the incident proton energy is converted into the energy of fast electrons via charged π meson decay, about 10 per cent appears in the form of gamma-ray photons from π° meson decay, and 15 per cent in the form of neutrinos. Some of the gamma-ray photons, which are of mean energy 50 MeV, should undergo secondary interactions in the nucleus, also producing fast electrons.

Electrons which escape into the envelope, where the strength of the galactic magnetic field is probably much less than inside the nucleus, should radiate at a lower energy level than they would if retained in the nucleus: perhaps the energy of most of these electrons is emitted in the radiofrequency continuum, while that of electrons retained in the nucleus is emitted in the optical continuum.

Whatever the mechanism of its production may be, radiation emitted from a galactic nucleus such as we have described is strongly affected by the gravitational field of the nucleus. For a nucleus which is capable of accelerating particles to a velocity of βc, the gravitational red-shift $(\delta\lambda/\lambda)$ of radiation emitted from its surface is $\frac{1}{2}\beta^2$. In order for this effect to be consistent with the Doppler ("cosmological") interpretation of the observed red-shifts associated with the quasi-stellar sources, we must assume that the emission lines of the optical spectrum are produced in material outside the nucleus, in regions where the gravitational potential of the nucleus is much lower than at its surface. Any gravitational red-shift which these lines may have is inextricably combined with the Doppler red-shift due to any radial component of velocity within the galactic material. We estimate that for a galactic nucleus having mass and radius as calculated, the gravitational red-shift for material at a distance of

only 10^{-1} parsec (pc) from the galactic centre is equal to the Doppler red-shift for velocities of the material of 10^3 km sec^{-1}.

Now the occurrence of velocities of 2×10^3 and 3×10^3 km sec^{-1} in the quasi-stellar sources 3*C* 48 and 3*C* 273 has been deduced by Greenstein and Schmidt[11] from the widths of emission lines from regions of diameter 10 pc and 1 pc, respectively. If the events inside and in close proximity to the galactic nuclei we have described are indeed related to the production of quasi-stellar sources, then the small gravitational red-shifts predicted may well be completely obscured by this additional observational feature of high velocities in the source material.

These emission lines, originating in the innermost region of the galactic envelope, are presumably excited by the electrons which escape from the nucleus. (An electron at a distance of 10 pc from the galactic centre has an energy of about 10 eV, and so is capable of inducing optical transitions in hydrogen and other light elements of the galactic material.) In general, it would seem that electrons which give up their energy at a large radius ($\gtrsim 10^{-1}$ pc) from a galactic centre provide a means whereby energy produced as the result of a gravitational process can be radiated without appreciable modification by gravitational red-shift.

The picture we now have representing high-energy events occurring in the galactic nucleus and its immediate environment is related by several common features to the model of quasi-stellar sources constructed by Greenstein and Schmidt[11] from detailed considerations of all the available observational data. On this model, a quasi-stellar source consists of three concentric regions: the first, of radius $\lesssim 1$ pc, gives rise to the optical continuum and may contain a central object of mass $\sim 10^9 M_\odot$; the second, of radius 1 pc–10 pc, is the source of the emission lines; and the third is an outer region from which the radiofrequency radiation is emitted. Observations by Smith and Hoffleit[22] of the variations in optical intensity of 3*C* 273 over a number of years have indeed indicated that the size of the optical component of the source is $\lesssim 1$ pc, at a conservative estimate, and could be much smaller, $\sim 10^{-2}$ pc (3×10^{16} cm).

Greenstein and Schmidt found that, in order to satisfy total energy requirements, for an estimated lifetime of 10^6 years for the quasi-stellar source and for a synchrotron emission model with equipartition between magnetic field and total particle energies, it was necessary to have a source of energy, possibly associated with the central massive object, which provided a steady supply of high-energy electrons. Now the process of catastrophic accretion which we have discussed is a mechanism by which this central massive object, if identified with the galactic nucleus of our model, could act as the required high-energy electron source. (Regarding the continuous generation of relativistic particles in, for example, the nucleus of 3*C* 273, we note the possible similarity of the nucleus in this respect to that of the Crab nebula, pointed out by Shklovsky[23], who suggested that if the two phenomena are similar in nature and differ only in scale, then there would be difficulties in explaining them on an accretion model[24].)

The length of time over which a galactic nucleus acts as a source of high-energy electrons cannot be estimated from our model alone. Electron production begins when the accretion process has produced an energy above the threshold for π meson production, and ends when the "stellar" evolution of the accreted material of the galactic nucleus has attained a stage beyond which the density of the material exceeds the limit corresponding to the meson decay condition. The lifetime of the source is, therefore, defined in principle; although it has not been estimated, because our own knowledge of the probable course of evolution of such a massive accretion is not at present sufficient.

After I had completed the work described here, I realized that Zel'dovich and Novikov[25] had considered a similar gravitational process—the accretion of interstellar material by a neutron star with the production of soft X-radiation. While the two gravitational processes are quite distinct, they are clearly of the same general type and form an interesting comparison.

The calculations made here have been based throughout on a model involving a number of simplifying assumptions, and may best be regarded as numerical illustrations of the working of our model. They do indicate, however, that in the process of catastrophic accretion of intergalactic hydrogen by the nucleus of a galaxy, highly localized sources of great energy may be produced; and they suggest that the nucleus, taken together with the innermost region (radius $\lesssim$ 10 pc) of the galactic envelope, could perhaps be identified observationally with the optical component of a quasi-stellar source.

The calculations also indicate that, with favourable conditions, such a source may occur at a phase during the lifetime of a galactic system having fairly typical properties. (Although I have taken a galaxy in a cluster as an example, I do not mean to suggest that quasi-stellar sources should necessarily be associated with clusters.)

It would be interesting to correlate stages of evolution of a galaxy with different stages of energy production on the accretion model. Both the total luminosity and the spectral distribution of the emitted radiation would be expected to change as the galactic material is continuously redistributed. I propose to investigate the consequences of the model when it is extended to cover such time variations of the system.

For the present I suggest that catastrophic accretion may be one possible mechanism whereby some of the gravitational energy of a galactic system is converted into electromagnetic energy, and that this conversion may operate through the intermediary processes of π meson production and decay.

I thank several former colleagues for much valuable discussion and constructive criticism, especially Dr. R. R. Hillier, of the H. H. Wills Physics Laboratory (University of Bristol) and Drs. P. Clegg, B. W. Davies and H. J. Sherman, of the Department of Physics, Queen Mary College (University of London), and also Mr. G. A. Falla, whose interest in astronomy provided the initial stimulus for this work.

LETTERS TO THE EDITOR

PHYSICS

High Elastic Modulus Carbon Fibre

PRESENT-DAY interest in fibre reinforced composite materials has been centred on the difficulty of preparing suitable filamentary materials in large quantities. The attractive physical properties of whisker crystals have not, as yet, been exploited, because of the difficulties of bulk production of uniform whiskers.

Of all filamentary materials, their physical properties give graphite whiskers greatest potential for composite development. Small quantities have been prepared and they are reported[1] to possess the highest tensile strengths (3×10^6 lb./in.^{2}) and Young's moduli (about 130×10^6 lb./in.^{2}) yet recorded for any material. In addition to this, the specific gravity is low (2·27) and the high strength and high modulus can be expected to be maintained to high temperatures. But, again, these whiskers are not amenable to bulk production by present techniques.

Carbon fibres are available commercially in relatively large quantities, but their tensile strengths and Young's moduli are too low (about 10^5 lb./in.^{2} and $5–10 \times 10^6$ lb./in.^{2}, respectively) for them to be of any significant use as structural elements in composite materials.

We have prepared carbon fibres of high elastic modulus in continuous lengths and in relatively large quantities, by precisely controlled heating of commercially available textile fibres to 3,000° C in both reactive and inert atmospheres. Average values of Young's moduli greater than 60×10^6 lb./in.^{2} with peak values more than 100×10^6 lb./in.^{2} have been attained. Average tensile strength values of 250,000 lb./in.^{2} are typical. Fig. 1 shows typical modulus and strength distributions. The specific gravity of such fibres is usually in the range 1·8–2·0. The tensile strength and modulus values reported for graphite whiskers indicate that these carbon fibre values are potentially capable of great improvement, but the present values are sufficiently high to make these fibres outstanding.

Effects of Long-chain Molecule Additives in Water on Vortex Streets

THE spectacular reductions of turbulent friction which can occur as a result of dissolving certain long-chain molecule substances in water[1] have still not been adequately explained. An explanation might be sought in terms of a continuum theory relating the stresses in the fluid to its motion. Various logically possible sets of such constitutive equations have been proposed, and both the second-order fluid of Coleman and Markovitz[2] and the anisotropic liquid of Ericksen[3] seem attractive as possible models of dilute polymer solutions. It is desirable, therefore, to try to devise simple experiments which will help to decide which model fits the real fluids best and determine the disposable constants in the theoretical model.

One of these constants in either model corresponds to the Newtonian viscosity as measured in conventional steady-flow viscometers. This must be equal to the viscosity of water for zero additive concentration, and in fact it varies comparatively little for concentrations of additive up to about 100 weight parts per million (w.p.p.m.). The other disposable constants would be expected to be linearly proportional to concentration for small concentrations.

As turbulence is a process dependent on time, it might be conjectured that the time-dependent terms in the theoretical models would be of particular significance with regard to turbulent drag reduction, and additions of different drag-reducing substances, in concentrations of roughly equal effectiveness for turbulent drag reduction, might all have been expected to produce similar effects on simple time-dependent flows. Further, these effects would seem likely to vary linearly with concentration. However, these reasonable expectations do not seem to be borne out, at first sight in any event, by the following experiments.

A suitable simple time dependent flow can be generated by a circular cylinder of diameter d placed transversely to a flow of speed v. As is well known, alternate eddies are regularly shed from the cylinder at a frequency n, forming a 'vortex street' wake, provided the Reynolds number vd/ν (where ν is kinematic viscosity) is in the appropriate range. In the present experiments the flow was a jet of circular cross-section and diameter 2·0 mm falling under gravity from a header tank, and the cylinder was a wire of diameter 0·15 mm placed transversely to the axis of the jet at a point where the gravity head was 15·7 cm, so that the speed was 1·76 m/s. Thus $R \simeq 240$ and the Strouhal number $S = nd/v$ ought to be about 0·17, according to Relf's results[4]. The eddy-shedding frequency was measured by a strain gauge element which sensed the small oscillations of a stylus 1·8 mm below the wire and in its wake. The results of measurements of the Strouhal number in water and various concentrations C (w.p.p.m.) of various drag-reducing additives are shown in Table 1.

Table 1. MEASUREMENTS OF THE STROUHAL NUMBER (S) IN WATER AND WITH VARIOUS CONCENTRATIONS (C IN W.P.P.M.) OF VARIOUS DRAG-REDUCING ADDITIVES

Water	S	0·15 – 0·17					
Polyethylene oxide (Union Carbide 'Polyox *WSR* 301')	C	5	10	15	20	30	40
	S	0·16	0·16	0·13	0·08–0·11	0·08–0·09	0·08–0·09
Polyacrylamide ('Dow Separan *NP* 30')	C	18	36	72			
	S	0·16	0·16	0·16			
Guar gum	C	80	120				
	S	0·15–0·16	0·16				

Small concentrations of all the additives made the eddy-shedding more regular than for water, where doubtless some breakdown of the vortex street into turbulence was beginning to occur. Presumably the additives inhibited this breakdown. However, as can be seen, larger concentrations of polyethylene oxide produced a large reduction in eddy-shedding frequency, quite unlike the behaviour of the other two additives, and far from linear in concentration. The large reductions in frequency were accompanied by proportionate increases in amplitude.

The threshold concentration of about 10 w.p.p.m. for polyethylene oxide, below which no reduction of the Strouhal number occurs, has no real counterpart in turbulent drag reduction. There—although there is a threshold shear stress which must be exceeded for drag reduction to occur[5]—the drag reductions are linear in concentration for small concentrations. It is conceivable that in the present eddy-shedding experiments there is some mechanism which tends to lock the Strouhal number to about 0·16 or some sub-multiple of this, as for concentrations greater than 20 w.p.p.m. the Strouhal number tends to about 0·08—half its initial value. Thus the present results do not entirely rule out a constitutive equation in which the coefficients are linearly proportional to concentration. Furthermore, the tendency for the lower frequencies to be favoured at the expense of higher ones is not inconsistent with the behaviour of turbulent flows, where the smaller eddies are suppressed[1]. However, polyacrylamide solution of 30 w.p.p.m. concentration or guar gum solution of 100 w.p.p.m. concentration would typically produce the same order of turbulent drag reduction as 15 w.p.p.m. polyethylene oxide solution, yet these fluids clearly do not behave similarly in the present eddy-shedding experiment.

All this suggests, perhaps, that various different mechanisms may be responsible for turbulent drag reduction. This conjecture is supported by normal-stress difference measurements in progress at this Division, which show that here again polyethylene oxide behaves differently from solutions of polyacrylamide or guar gum of equal turbulent drag reducing potency.

Turbulent-flow Properties of Deoxyribonucleic Acid Solutions

MANY natural and synthetic high polymer solutions have lower friction in turbulent flow than the pure solvent[1]. In an effort to devise an experiment to explain the mechanism involved, flow studies were made using deoxyribonucleic acid (DNA) together with various carcinogens, steroids, acridine dyes, an antibiotic, and other materials which modify the effective molecular size, shape, and weight of the dissolved DNA. While the mechanism of friction reduction is still as elusive after these experiments as before, the interesting differences in turbulent flow properties of the various DNA-additive complexes may point to a simple way of estimating the effects of additives on the configuration of the DNA molecule.

An apparatus for measuring the turbulent-flow properties of fluid samples, based on the change in pressure loss due to pipe friction compared with that of distilled water, was used for the DNA tests[2,3]. This instrument gives an indication of the friction-reducing properties of high polymer solutions. The test consists of measuring the pressure drop in a section of small pipe at constant flow rate corresponding to a Reynolds number of 14,000, first with distilled water, then with the test solution. Then the friction reduction can be calculated using the relation:

$$\text{Percentage of friction reduction} = 100\,(1 - \Delta P_t/\Delta P_w)$$

where ΔP_t is the pressure drop using test solution, and ΔP_w is the pressure drop using distilled water.

All chemicals were commercially obtained, as well as the calf thymus DNA (Sigma Chemical Co.), and were used without further purification. The tests were made at 23° C, with a 0·15 M sodium chloride, 0·015 M sodium citrate, *p*H 7·0 solution as the solvent. This solution shows no difference from distilled water in flow characteristics in the test apparatus. Additives which dissolved in this solvent (no DNA present) did not affect the friction properties.

Fig. 1 shows the results obtained for DNA and for DNA mixed with steroids, a purine, and a mustard. In each case a weight of chemical equal to half the weight of DNA in solution was added and stirred at 23° C for at least 1 h before testing. While DNA itself seems to be a very effective material in terms of reducing the turbulent

friction, mixtures of DNA plus these chemicals showed little consistent change in effect. From these data it would seem that the binding[4,5] of 17β-oestradiol, testosterone, caffeine, and *tris*(2-chloroethyl) amine has little effect on the flexibility or other structural characteristics of DNA.

The dyes 9-amino acridine and proflavine showed large increases in friction reduction (Fig. 2) when mixed with DNA. These materials are believed to intercolate strongly in the DNA helix[6], extending the length of the molecule. Repeated frictional tests show that these materials also greatly strengthen the DNA to shear degradation.

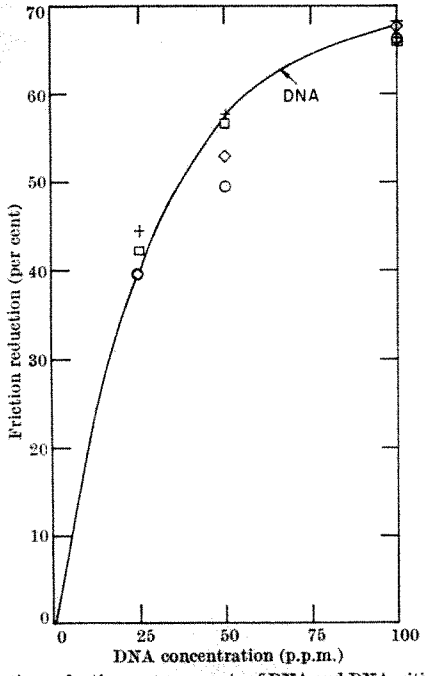

Fig. 1. Friction reduction measurements of DNA and DNA with steroids, a purine, and a mustard, as a function of DNA concentration. ○, 17β-Oestradiol; □, testosterone; +, caffeine; ◇, *tris*(2-chloroethyl)amine; —, DNA alone

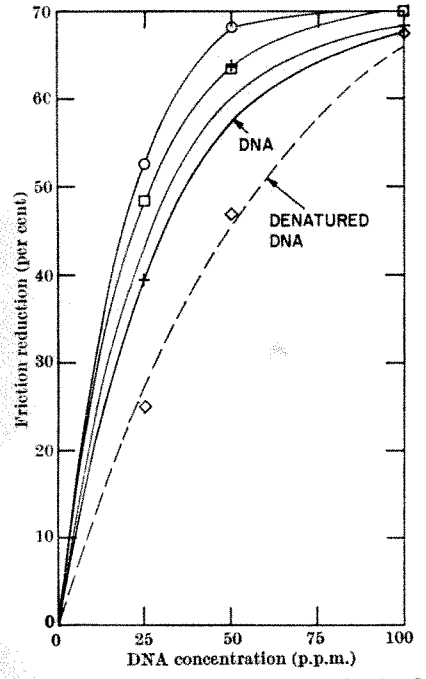

Fig. 2. Friction reduction measurements of DNA, denatured DNA and DNA with acridine dyes and an antibiotic as a function of DNA concentration. ○, 9-Amino acridine; □, proflavine; +, actinomycin-*D*; ◇, acridine orange; ——, DNA alone; — —, denatured DNA

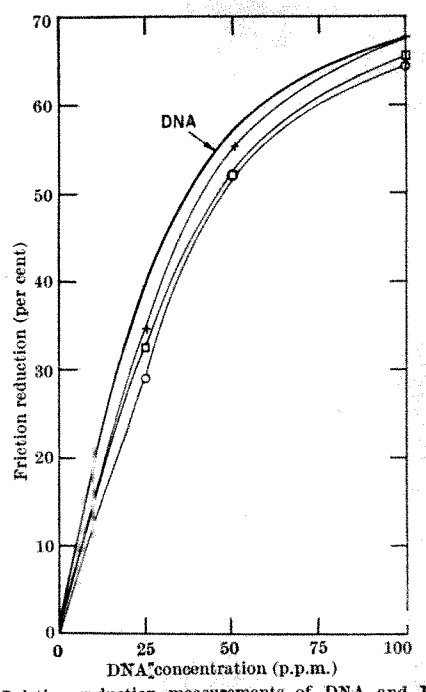

Fig. 3. Friction reduction measurements of DNA and DNA with carcinogens and a hydrocarbon as a function of DNA concentration. ○, 3,4-Benzpyrene; □, 1,2,5,6-dibenzanthracene; +, phenanthrene; —, DNA alone

Actinomycin-*D* also exhibits the same characteristics with DNA although the binding may not involve intercolation in this case[7]. In contrast, acridine orange seems to intercolate[8] to such an extent as to separate the DNA helix components so that the friction-reduction of this mixture was practically identical to that of a DNA preparation which had been denatured by bringing a water solution to 90° C and rapidly cooling.

Tests with the carcinogens 3,4-benzpyrene and 1,2,5,6-dibenzanthracene (Fig. 3) indicated substantial lowering of the friction reduction effect. I surmise this is due to a partial unwinding of the helix or at least a weakening which allows mechanical shear partially to separate the helix pairs. These materials seem to act by intercolation[9] and the test data show that phenanthrene which is a near carcinogen by several measures[10] may act in almost the same fashion.

In summary, the method of measuring the turbulent friction resistance of DNA-complexes may offer some insight into the changed structural characteristics which occur. Since the method requires such simple apparatus, it seems that refinement of the technique may be of value in further investigations of the physical effects of additives on the DNA molecule.

I thank Lt. M. F. Hayes, of the Naval Postgraduate School, Monterey, California, who performed these experiments during a summer assignment at this Station, and Dr. H. D. Brown, of Merck, Sharp and Dohme Research Laboratories, for a gift of 'Dactinomycin'.

Growth of Ice Tubes

IT has been known for many years that when supercooled water suddenly freezes, whisker-like growths may occasionally form on the upper side of the layer of ice covering the water. It would seem that this was first reported by H. G. Dorsey in 1921 (ref. 1), but it has since been mentioned by several other observers[2–6].

Two theories have been put forward to account for the whisker-like growths. The earlier observers thought they were produced by reverse sublimation, that is, the capture of vapour molecules by the ice, and it was suggested that they might even be of single-crystal form. Bally[4], however, argued that the needles might, in fact, be tubes of ice with a core of water. Unfortunately, their small size (diameters a few tenths of a millimetre and lengths up to about a centimetre are typical), and the fact that neither the time nor the place of their sudden appearance can be predicted, have hitherto prevented detailed observation of their growth so that direct evidence of the growth mechanism has been absent.

A new method of cultivating these growths was discovered in the course of other work, which results in specimens up to an order of magnitude larger than those grown by the conventional method. These large growths have been filmed, and this has provided conclusive evidence that Bally's 'tube' theory of growth is correct.

The growths are formed in a vacuum from frozen deaerated water. About 50 ml. of distilled water contained in a beaker is vigorously agitated with a vibrating stirrer, inside a vacuum chamber where the air pressure is reduced to about 0·1 mm mercury absolute. Under these conditions the water boils vigorously at room temperature, and the air previously dissolved in the water is extracted. Then the stirrer is switched off, and the vacuum is momentarily released. This sudden increase in pressure forces any traces of undissolved air into solution in the deaerated water, thus removing any nuclei that might later have initiated boiling.

When the vacuum is restored the water does not boil but enters the metastable region, where the pressure is below the saturated vapour pressure, that is, it becomes superheated. When the stirrer is in action it promotes vigorous agitation in the water, which still does not boil but remains in a superheated state. This may seem surprising in view of the widely held belief that metastable conditions in water are disrupted by vigorous agitation. Numerous experiments in this laboratory have shown, however, that agitation has no effect on a moderately superheated liquid, or even on a liquid under moderate negative pressure—provided that gas nuclei have been completely removed and that the agitation is not such as to introduce fresh nuclei.

In this condition of agitated superheat, rapid evaporation occurs. This cools the water progressively, and after a few minutes its temperature falls well below freezing

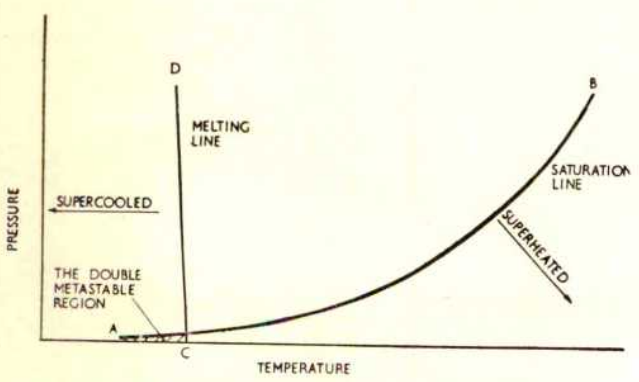

Fig. 1. Graphical representation of the double metastable state in liquid water (supercooling-cum-superheating)

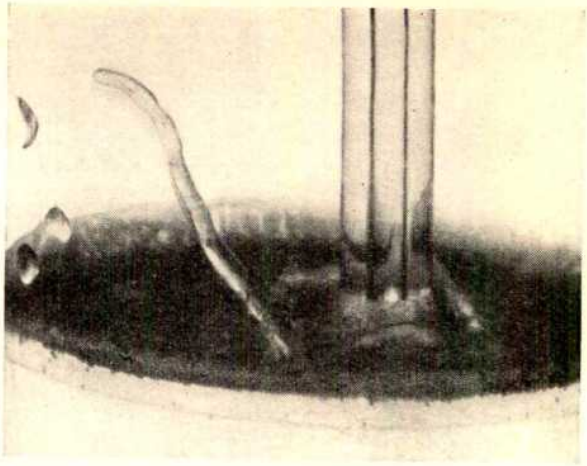

Fig. 2. Typical ice-tube formation. (The stirrer rod is 0·25 in. in diameter)

point. The water is then doubly metastable: it is both superheated and supercooled, simultaneously.

This condition is illustrated in Fig. 1. The region below the saturation line AB corresponds to the superheated state, while the region to the left of the melting curve CD corresponds to the supercooled state. Consequently, the shaded area, which is below AB and to the left of CD, corresponds to the double metastable state, where the liquid is both superheated and supercooled. If seeded with an ice crystal it will freeze, but if seeded with a gas bubble it will boil.

When the temperature of the water falls to about $-10°$ C, spontaneous freezing occurs. A solid disk of ice forms on the surface, and a network of ice crystals interspersed with water forms beneath. After a period which may be anything from a few seconds to a few minutes, an ice needle may grow rapidly from the upper surface of the ice.

The needles may take a wide variety of forms. A needle may be straight or gently curved as in Fig. 2. It may bend very sharply, and even bend through 180° until it ends by returning to the ice surface from which it emanated. Needles grown by this method are usually between 2 mm and 3 mm in diameter, and up to 5 cm long; their rate of growth is of the order of 1 cm per sec.

The growth of a number of these large specimens has been filmed at 50 frames per second, and when the film is projected at 24 frames per second it can be seen that the 'needles' are, in fact, hollow tubes of ice with a core of water, as was conjectured by Bally[4]. This is most clearly apparent at the moment of cessation of growth, when the core of water can be seen to freeze. Sometimes the wall of the tube can be seen to burst, under the pressure generated by the freezing of the water inside it.

While a tube is growing its tip is hemispherical in shape, and the surface of the hemisphere can be seen to pulsate. It is evident that the tip consists of an unfrozen drop of water. The outer edges of this drop of water rapidly freeze, thus progressively lengthening the walls of the tube, while the drop is continuously replenished by fresh water passing up the inside of the tube.

Pressure is obviously required to force the water up the tube. This pressure is evidently generated by the expansion of water as it freezes slowly in the enclosed space between the upper disk of ice and the walls of the beaker. That this is so may be seen by using a slightly contaminated beaker for the experiment; in this case the disk of ice does not adhere perfectly to the wall of the beaker, no pressure is generated, and an ice tube does not form.

A film of these experiments, complete with a sound commentary, has been prepared and may be borrowed

on application to the Director, National Engineering Laboratory, East Kilbride, Glasgow.

Technique for the Measurement of the Transit Time of an Optical Signal

DURING the past several decades numerous arrangements have been developed for measuring the time of transit of a beam of light propagated over a tropospheric path. In these arrangements the transit time is determined by measuring the phase shift of modulation on the beam[1–6]. Most of this work has been carried out in connexion with measurements of (1) the velocity of electromagnetic waves, (2) geodetic distances, and (3) atmospheric turbulence.

This communication presents still another configuration for such phase measurements by combining elements found in several of the approaches already referred to. The combination described here appears to possess several characteristics which might, in certain applications, provide improved performance compared with those suggested in the literature to date.

The suggested scheme is similar to the techniques described by Bergstrand[1] and that used by the Central Radio Propagation Laboratory at microwave frequencies since 1955[7,8]. In fact, it may be considered to be the latter technique modified to propagate the microwave measuring signal as polarization modulation on an optical frequency carrier rather than by direct radiation and reception of the microwave signal. The principal differences between this technique and the one used by Bergstrand are the heterodyning process for reducing the measuring signal to lower frequencies and the use of direct linear phase comparison.

The basic system is shown in Fig. 1. At terminal 1 a light beam is polarization modulated by modulator 1 and transmitted along the path to terminal 2, where it is modulated again by modulator 2. The modulating signal at terminal 1 is obtained from a stable reference oscillator operating at frequency f_1 of, say, 10 GHz. The modulating signal at terminal 2 is obtained from a voltage-controlled oscillator the frequency (f_2) of which is chosen such that $f_2 - f_1 = f_t$, where f_t is, say, 50 kHz. The polarization modulation is then converted to intensity modulation by polarizer 2.

The intensity-modulated light emerging from polarizer 2 has a component at frequency f_t which is detected and converted to an electrical signal by photodetector 2. This intermediate frequency (IF), f_t, is compared in the phase detector with a 50 kHz signal generated at terminal 2 by the IF reference oscillator. The output from the phase detector is applied as an error signal to the voltage-controlled oscillator. This phase locks the voltage-controlled oscillator to the microwave modulation on the incoming light beam and ensures that $f_2 - f_1 = f_t$.

Simultaneously, a light beam is transmitted from terminal 2 to terminal 1. This beam is first modulated by modulator 2, transmitted along the path, then passed through modulator 1 and polarizer 1. When this beam emerges from polarizer 1 it also has a component of intensity fluctuation at frequency f_t, which is converted by photodetector 1 to an IF signal of frequency f_t. This IF signal is returned to terminal 2 for phase comparison with the IF signal generated by photodetector 2.

Except for a constant term, the phase difference between the IF signals generated at terminals 1 and 2 is equal to the phase difference of the modulation signals travelling along the path, and thus provides a measure of the transit time. Since the same analysis applies here as applies to the Bergstrand and Central Radio Propagation Laboratory systems referred to above, this aspect will not be repeated.

The polarization modulation of the light beams is accomplished by the common technique in which the original beam from the source is passed through a polarizer and an element the birefringent properties of which depend on an electrical potential (Kerr cell, Pockel cell, etc). Aside from focusing and intensity considerations, the coherence properties of the beam itself have no particular significance for this application.

By the use of a single transit of the beam over the path, more light power and less scintillation are achieved than with systems in which the beam is reflected back over the path to the point of origin[9]. For an order of magnitude calculation, assume a collecting aperture diameter of 20 cm, divergence of 0·1 milliradian for the beam (representative of a laser beam: the relative improvement realized in the case of a wider beam is correspondingly greater), and the atmospheric attenuation of 0·5 dB/km. There results an increase of light intensity given by:

$$(P_1/P_2) = (0{\cdot}5L + 20 \log 0{\cdot}5L) \text{ dB}$$

where L is the path length in kilometres, P_1 is the light intensity available at the photodetector for a one-way

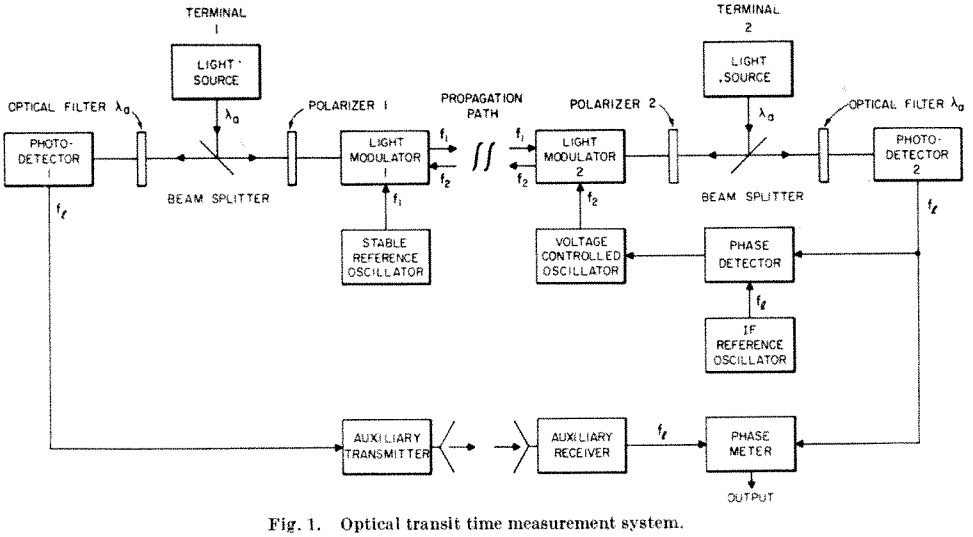

Fig. 1. Optical transit time measurement system.

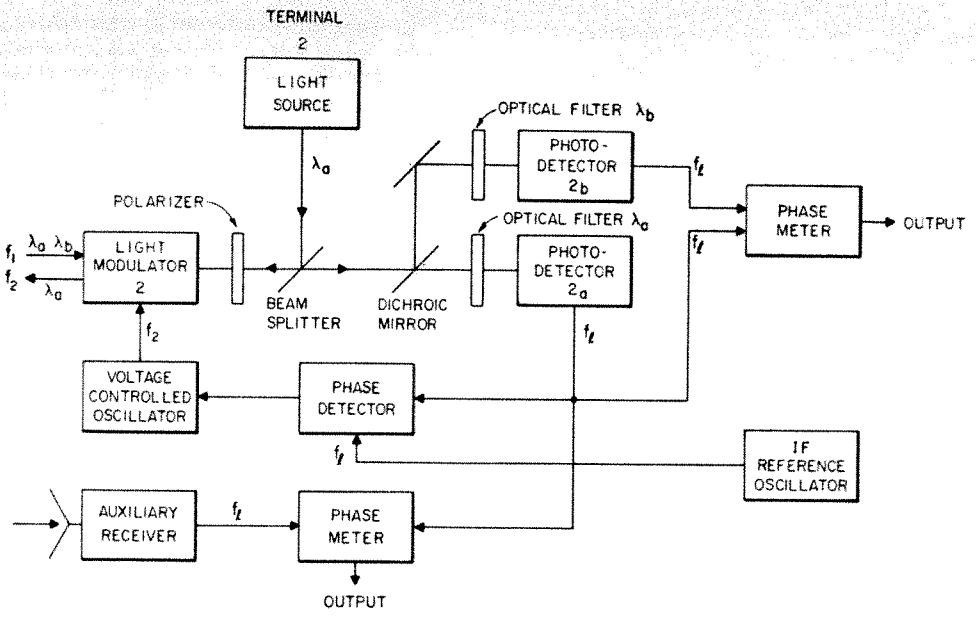

Fig. 2. Modification to permit determination of atmospheric dispersion

transmission, and P_2 is the light intensity available at the photodetector after reflexion back over the path. The first term on the right-hand side arises from the attenuation of the light beam in the atmosphere. The second term expresses the fraction of the beam area intercepted by the collector at the terminal where it is received and assumes that the latter lies completely within the former. For a 10-km path (P_1/P_2) is about 19 dB, for 20 km about 30 dB, and so on. This does not take into account reflexion losses.

This gain in received light intensity is purchased at the cost of providing the auxiliary link, but the essential problems involved in obtaining a suitable link have been solved already[7]. Other advantages include the use of linear phase measuring with its attendant simplicity, accuracy, and high-frequency response and the absence of variable light paths, obviating problems of depolarization by additional optical elements.

The upper value to the modulation frequency may be limited by the state of available modulators to frequencies no higher than a few GHz for continuous operation. Pulse operation may be required for higher frequencies.

The use of a second telescope and modulator might appear to be a disadvantage compared with some systems[4,10,11]. However, these systems have a back-scatter problem which may be quite serious. In this arrangement, because of the increased received light intensity compared with a system using a reflector at one terminal, back-scatter should be accordingly less important. Furthermore, back-scatter can be further reduced in this system by the use of nearly monochromatic light sources at slightly different wave-lengths and the appropriate narrow-band optical filters before each photodetector.

In the measurement of geodetic distance through the troposphere one of the more serious difficulties is the determination of the average refractive index along the path. It has been suggested[9,12] that the atmospheric dispersion in or near the visible portion of the spectrum is large enough to be useful in determining this average refractive index.

The extension of this system to include the measurement of atmospheric dispersion is relatively straightforward as shown in Fig. 2. The source at terminal 1 supplies light at the two wave-lengths desired. This may be achieved by using a source which generates spectral lines and optical filters to select those lines desired. It might also be accomplished by combining, optically, light from separate sources. At terminal 2, the incoming beam containing both light wave-lengths is passed through modulator 2, where the modulation on each is heterodyned to the IF frequency. The voltage-controlled oscillator is phase-locked as before to one of the incoming signals. By means of the narrow-band optical filters each of the photodetectors responds to the modulation on the corresponding component of the incoming beam. The phase shift between these photodetector output signals will be proportional to the dispersion of the propagation path. As discussed in the references, this information can then be used to correct the path length indicated by the first part of the system.

ASTROPHYSICS

Radio Astronomical Detection of Helium

WE report the detection of three radio lines arising from transitions between highly excited states of neutral helium (^{4}He). The observations were made with the 60-ft. telescope of Harvard University during the months February–April 1966. The observed helium lines result from transitions of the $n + 1 \rightarrow n$ type between states 160 and 159, 159 and 158, and 157 and 156. Conforming to the notation suggested in our recent work[1] on excited hydrogen, we shall call these transitions 'He 156α',

'He 158α' and 'He 159α', respectively. Their respective rest frequencies are 1716·372 Mc/s, 1652·214 Mc/s and 1621·332 Mc/s. (Adopting a more recent value of the Rydberg constant R_∞ (ref. 2), the rest frequencies of the lines reported in our previous reports (refs. 1, 3) are slightly modified. The frequencies for H 156α, H 158α and H 166α are 1715·673 Mc/s, 1651·541 Mc/s and 1424·734 Mc/s, respectively.)

The Harvard 60-ft. telescope is equipped with a cavity maser ten-channel radiometer having a frequency resolution of 80 kc/s. The antenna beam-width is 52 ± 2 min of arc and the aperture efficiency is 0·38 ± 0·02 over the range of frequencies utilized. The total noise temperature of the system is about 100°K.

Fig. 1 shows the H 159α and He 159α profile obtained in 14 h of integration time. Also included is a profile of the He 158α line with 21 h of integration time. The zero level of the He 158α data is arbitrarily elevated for visual comparison. Fig. 2 is the profile of a comparison source, Taurus *A*, obtained over the same frequency range as the 159α profile shown. The theoretical separation of the H 159α and He 159α lines is 0·660 Mc/s and this value has been indicated on Fig. 1 by the vertical lines through the hydrogen and helium features.

We have considered the possibility that the helium signals are produced by another atomic or molecular species. Because we have observed the helium line at three different frequencies we can exclude the possibility that these are anything other than $n\alpha$ type lines. The total abundance of all the elements other than hydrogen or helium has been estimated by a number of methods to be of the order of 1 per cent of the total mass of the galaxy and, if so, they will not produce $n\alpha$ type signals of sufficient intensity to be measured by our telescope. We have calculated the frequencies of the H $n\beta$ and H $n\gamma$ transitions which lie near the frequencies of the three helium lines and find that they do not coincide with our observed signals. Furthermore, the normal theory of differential galactic rotation would exclude the possibility of an HII region having a radial velocity of ~ -100 km/s in the direction of *M*17. While we cannot rule out the possibility that an HII region with an extremely large peculiar velocity lies along the line of sight to *M*17, the Doppler shift must be exactly the separation of the He $n\alpha$ and H $n\alpha$ lines in this frequency range, a coincidence we regard as unlikely.

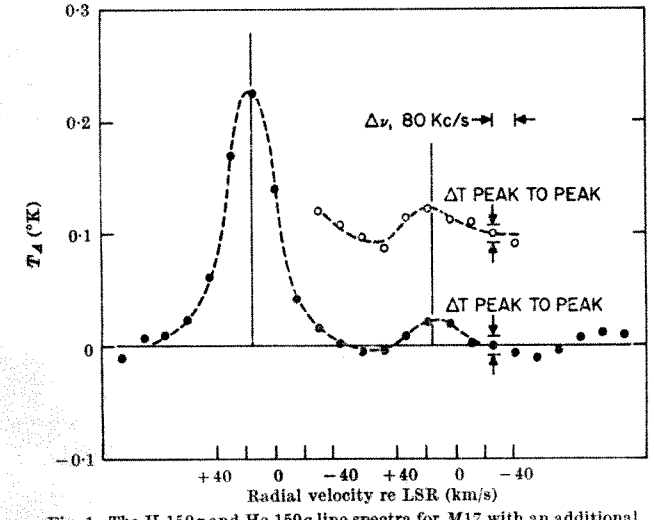

Fig. 1. The H 159α and He 159α line spectra for *M*17 with an additional set of ten-channel data covering the He 158α line. The ordinate is antenna temperature and the abscissa is velocity with respect to the local standard of rest. The continuum antenna temperature of *M*17 is 20° K. ●, 159α, 14-h integration; ○, 158α, 21-h integration

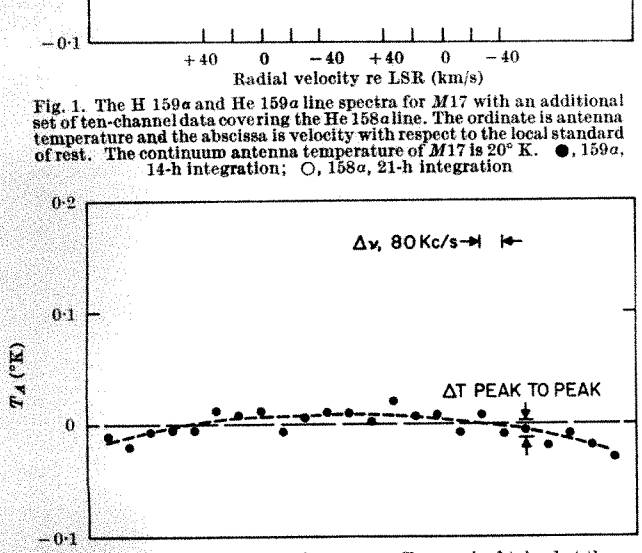

Fig. 2. The spectrum of a comparison source, Taurus *A*, obtained at the same frequency range used in the 159α measurements on *M*17. The continuum antenna temperature of Taurus *A* is 29° K. 18-h integration

For a system capable of achieving larger signal-to-noise ratios for the helium lines (preferably at much higher frequencies where the line strengths are greater), simultaneous measurements of hydrogen and helium should yield several important quantities. First, a comparison of helium and hydrogen line widths should make it possible to separate the thermal and turbulent velocities of the nebulae. Secondly, the data in most cases provide a measure of the helium to hydrogen abundance ratio in HII regions, a quantity of cosmological interest.

If the hydrogen and helium share the same thermal and turbulent motions, and if these are the only broadening mechanisms of importance for $\nu > 1{,}420$ Mc/s (as we believe to be the case[1,3]), then with sufficiently large signal-to-noise ratios, we have a possible method for determining the electron temperature and turbulence in the nebula. However, the accuracy of the method depends on the relative magnitude of the turbulent and thermal contributions to the observed line widths. This method would be important because of the apparent disagreement between optical temperature determinations (see, for example, O'Dell[4]) and recent radio determinations of nebular electron temperatures[1,3,5] following the method suggested by Kardashev[6]. Recent work by Goldberg[7] has shown that determinations of electron temperatures by the method suggested by Kardashev may be inaccurate in some cases. Thus, the method utilizing the hydrogen and helium line widths may be the only way to determine electron temperatures from the $n\alpha$ line results.

We have planimetered our *M*17 profiles and obtained a mean ratio of the area under the helium line to that under the hydrogen line equal to 0·10 ± 0·05. Two principal effects must be evaluated before this quantity can be related to the abundance ratio of helium to hydrogen. Because the degree of ionization of hydrogen and of helium is controlled by the radiation field of the exciting stars in the nebula and not by the electron temperature, one should examine the radio lines of both neutral and ionized helium to determine the total helium abundance. If the exciting stars are relatively cool[8], the fact that the Stromgren spheres for helium and for hydrogen are different must also be taken into consideration. With these factors accounted for, it will be possible to obtain the helium : hydrogen ratio from the radio profiles.

Radio Emission of Venus at 3 cm and the Solar Activity

BECAUSE of the favourable observing conditions, the planet Venus has frequently been observed in the radio spectrum for some years now. Recently, precise observations at the wave-length 3·3 cm were made by Bibikova *et al.*[1]. These observations were made after the inferior conjunction in Summer 1961. The authors found that the temperature of the planet was distinctly dependent on its phase. The mean temperature observed was about 544° K for the mean phase 0·47, and the value derived from the phase dependence for the inferior conjunction was found to be about 372° K. This large day–night contrast in temperature gives some support to Sagan's[2] greenhouse model over Opik's[3] aerospheric model of the Venusian atmosphere.

Bibikova *et al.* have also compared their results with those obtained by Mayer *et al.*[4] for the 1958 conjunction. For the temperature difference of about 100° K between the two inferior conjunctions, they admitted (in one of their two suggested hypotheses) the possibility that the difference found may be caused by solar activity, because the observations were made at different phases of the solar cycle.

As can be seen from the data of Bibikova *et al.*, the differences between the individual temperature values are in some cases greater than their mean error. Thus the variability of the observed temperature must be real and an adequate explanation of this phenomenon must be sought.

We have therefore investigated the possible dependence of the Venusian temperature as given by Bibikova *et al.* on the instantaneous solar activity, represented by the daily Wolf's numbers R. When making correlations the longitude differences of the Earth and Venus must be respected. Because of the rotation of the Sun, this difference gives a shift in phase in the scales of the time of observation of the solar activity on the Earth and the influence of the activity on Venus. We therefore corrected all the dates of observations of Venus (t_φ) for this geometric effect and obtained fictitious dates (t'_φ) suitable for correlating the Venusian temperature T_φ with R. To obtain a good correlation between the curves of T_φ and R the T_φ curve must be shifted to the left by about 8–9 days. The result using a supplementary shift, Δt, of 8·5 days is given in Fig. 1. In this case the ratio $\Delta T/\Delta R$ is about unity, and for $R = 0$ the dependence of T_φ on the phase of the planet disappears. The resulting value for the temperature, reduced to the conditions without solar activity, is $T_\varphi = 475°$ K.

In order to confirm this finding we have made a short analysis of the observations made by Mayer *et al.*[5] at λ3·15 cm during the 1956 inferior conjunction. The dispersion of the temperature values was greater in this case, and the correlation was not as detailed, but the results correspond in general to those for the 1961 conjunction. Only the reduced temperature for zero activity was lower and was estimated to be about 440° K. A more complete analysis of the dependence of Venusian temperature on solar activity, using data published by different authors for other frequencies, will be published elsewhere[6].

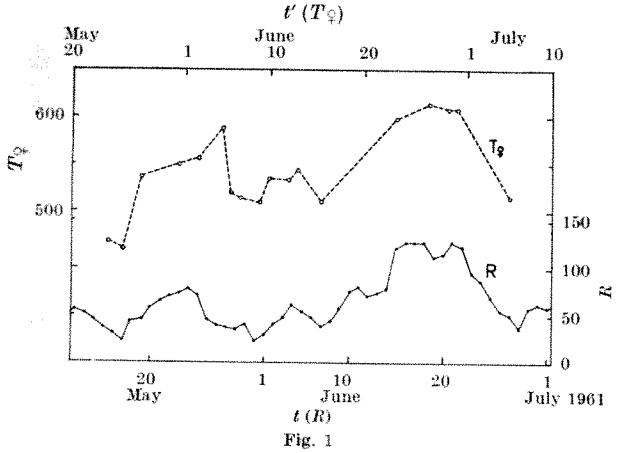

Fig. 1

In both the cases mentioned the trend of solar activity was decreasing in the direction of the conjunction (in 1956 observations were made before and in 1961 after the inferior conjunction). This led Bibikova *et al.* to suspect that the temperature was dependent on the phase of the planet. The actual independence of temperature from the phase suggests a high speed of rotation. However, the rotation of a planet with an atmosphere must induce a general circulation, with transport of energy through the atmosphere. It is very difficult to compare present models of the Venusian atmosphere with existing radio measurements, as has been shown by Danilov[7] and Jastrow and Rasool[8]. The dependence of the observed temperature on the solar activity indicates that the influence of far-ultra-violet and X-radiation, produced by the hot active regions in the solar corona, must now be taken into account in the construction of the models of the Venusian atmosphere. The most difficult aspect of this problem is the great retardation of about 8 days in the transformation of the radiation energy from the active regions into thermal energy in the form of radio emission from the planet.

More systematic, detailed and accurate observations at different wave-lengths during the rising part of the commencing solar cycle are now needed in order to verify the present results and to obtain more information on this phenomenon at other wave-lengths.

Observations of the Low-energy Photon Fluxes during the Solar Approach of the Ikeya-Seki Comet

A BALLOON-BORNE omnidirectional scintillation detector was aloft over Palestine, Texas (L value about 1·6), during the solar approach of the Ikeya-Seki comet on October 20, 1965. One of the aims of this experiment was to observe any possible enhancements to the low-energy atmospheric photon flux induced by the passage of the comet. The perihelion of the comet occurred on the 'dark' side of the Sun with an orbital inclination of about 40° to the ecliptic and therefore had an apparent perihelion of about 1° around the Sun as observed from the surface of the Earth.

The detector consisted of a cylindrical sodium-iodide (thallium doped) scintillator of diameter 5 in. and depth ½ in., yielding a geometric factor for an isotropic flux of 76·2 cm². The axis of the detector was vertical, and a 5 in. photomultiplier tube observed the scintillations from below. Pulse height analysis techniques (which were compatible with FM/FM telemetry systems on both the balloon package and the ground station) enabled a study of the atmospheric photon component in the energy intervals 100 keV–325 keV, 100 keV–660 keV, energies

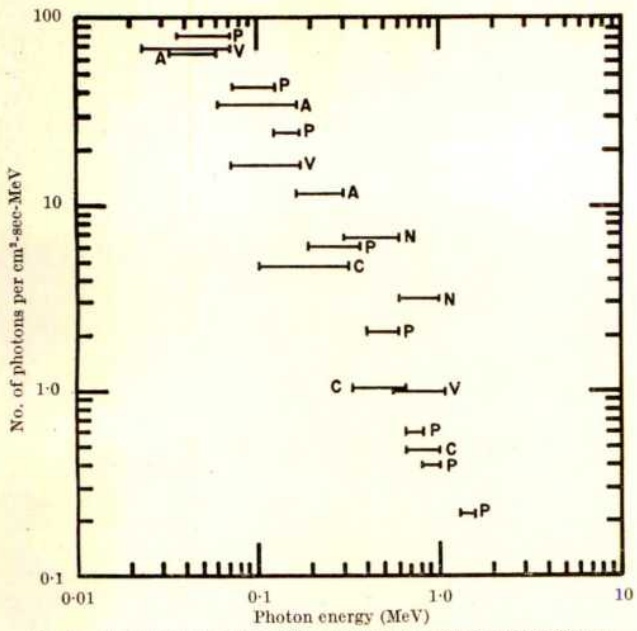

Fig. 1. A comparison of the differential photon fluxes obtained in the present investigation with those obtained by previous workers. The altitudes at which the various spectra were obtained are as follows: *P* (Peterson), 6 gcm^{-2}; *V* (Vette), 5·4 gcm^{-2}; *N* (Northrop *et al.*), rocket; *A* (Anderson), 6·5 gcm^{-2}; *C* (present results), 8·8 gcm^{-2}

above 660 keV, and 325 keV–660 kev (the details of this latter channel, which includes the positron annihilation photons, will be the subject of a later publication). At the float altitude of 8·8 gcm^{-2} the differential photon energy spectrum was determined to have the exponent $\left(-1{\cdot}80\ ^{+0{\cdot}2}_{-0{\cdot}1}\right)$.

Fig. 1 compares the results of some of our differential fluxes with the results of previous workers such as Peterson[1], Vette[2], Northrop and Hostetler[3], and Anderson[4]. It is readily seen from Fig. 1 that our results agree very favourably with the previously measured fluxes, albeit the latter were determined at slightly higher altitudes. In fact, this excellent agreement (any departures certainly lying completely within the differences in detector responses) is reason for concluding that the solar approach of the Ikeya-Seki comet produced no significant effects on the atmospheric photon flux.

GEOLOGY

Devonian Fishes from Kashmir, India

THIS communication reports the finding of fragmentary remains of Devonian fishes from India. They were collected by one of us (V. J. G.) *in situ* near Margan Pass (33° 44′ N., 75° 32′ E.) in the Anantnag District of Kashmir, India. They were discovered in dark, calcareous shales that overlie the fossiliferous Naubug Beds and underlie the Muth Quartzite, which is exposed on the talus-covered slopes south-west of Mangan. The former are of Upper Silurian age, while the Muth Quartzite near Naubug has been assigned to the Middle Devonian.

The first specimen (Fig. 1) consists of crowded and stacked skull plates and scales. The plates are thick and their surfaces perforated by numerous pores—as in the cosmine of crossopterygians and lungfishes. They have a middle layer with numerous small canals or cavities, and a thick, clearly laminated basal layer. A few of the skull plates are only slightly displaced from their original articulation, and their small size in relation to the scales suggests that we are dealing with a primitive lungfish. These plates are comparable with, though not definitely identifiable with, plates of the *Dipterus* cranial roof; possibly they are X, Y_1, Y_2 and I_2, J of White's terminology[1]. They have relatively large lateral line pores, and the possible I_2 has a widely open pit-line groove. Other skull plates have not been determined even provisionally. The scales are broken but would seem to have been relatively large, thin and cycloidal. On part of their external surface they show fine radiating ridges which resemble those of the overlapped areas of *Dipterus* scales. One small area has more widely spaced, subparallel, fine ridges on a meshwork base; this resembles the exposed area of scales of a specimen of *Dipterus valenciennesi* (Field Museum, *PF* 1294) in which the cosmine layer is absent. The Kashmir specimen is without doubt a lungfish, probably of the family Dipteridae, but the genus and species must remain undetermined.

The other specimen (Fig. 2) shows scattered scales, a few of which are still articulated. The scales are smooth, more or less rhombic, and have an outer surface that is shiny and pierced by numerous fine pores as in cosmine. The anterior, overlapped area is relatively broad and lacks cosmine. These scales probably belong to a crossopterygian of the family Osteolepididae, but cannot be identified more specifically. The opposite surface of the same specimen shows a small part of a tail in which are

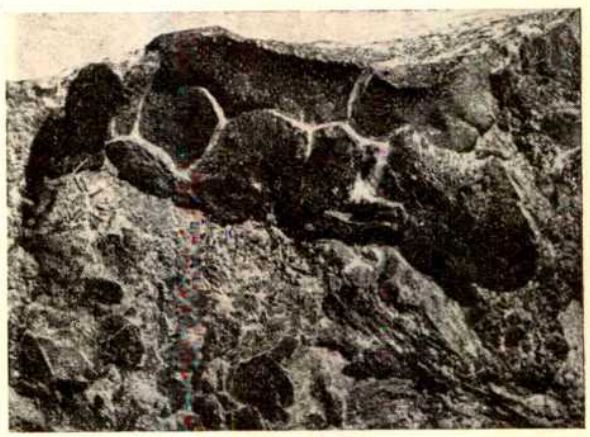

Fig. 1. Devonian lungfish from Kashmir, plates of cranial roof and broken scales (× *c.* 4)

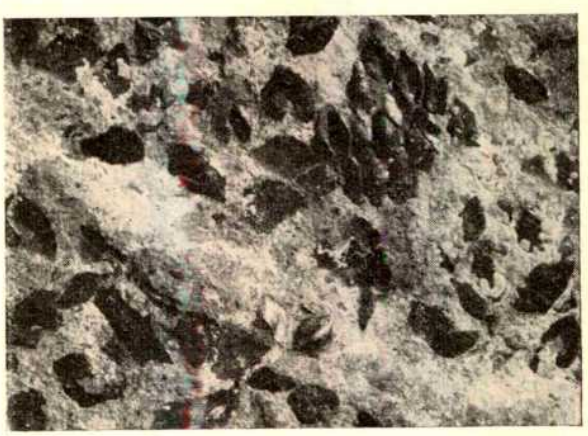

Fig. 2. Scales of a probable osteolepid (× *c.* 4)

preserved a few scales and fin rays. It is possible that it belongs to the same type of osteolepid.

These fishes are similar to the Middle Old Red Sandstone fishes of Scotland and suggest a Middle Devonian age for the shales which contain them. It is interesting that these shales have a very close lithologic resemblance to some of the beds of the Middle Old Red Sandstone, particularly of the Thurso Flagstone Group of Caithness, Scotland. The finding in India of osteolepids and dipterids, both typical families of fresh-water fishes, is of considerable palaeogeographical importance.

Standard Cenozoic Stratigraphic Zonal Scheme

IN 1957 Bolli[1–3] published a detailed account of twenty-nine planktonic foraminiferal zones for the Trinidad Cenozoic. These zones have now been recognized and have been widely used in the stratigraphy of many other tropical and also to a lesser extent in the temperate regions[4–7]. I would like to comment briefly on a drastic revision and modification of Bolli's zonal scheme recently published in this journal[8].

One of the best documented evolutionary lineages in the Miocene planktonic Foraminifera was first described by Bolli[9] and is known as the *G. fohsi* lineage. Later, Banner and Blow[10] called it "the well known evolutionary lineage" and they provided considerable supporting evidence for the lineage in the form of excellent photomicrographs which demonstrated the development of the peripheral keel in the succeeding taxa. Banner and Blow[8] have now apparently revised the *G. fohsi* lineage to such an extent that none of Bolli's four original zones, based on the *G. fohsi* lineage taxa, appear in their revised zonal scheme.

In another communication[11] I have demonstrated to Banner, Blow and their colleagues that in the New Zealand Lower Miocene, *Globoquadrina dehiscens* appears stratigraphically lower than *Globorotalia kugleri*. A similar succession of species has also been reported by Wade[12] in South Australia. How then is it possible for "*G. dehiscens praedehiscens*" to evolve into "*G. dehiscens dehiscens*" after the extinction of *G. kugleri* in Zone N.5 as reported by Banner and Blow[8]? The co-authors[8] claimed to have examined Australian and New Zealand fossils, but they have obviously chosen to ignore well-documented published evidence of the stratigraphic succession of planktonic foraminiferal species from the Australasian region[13–15].

The use of *nomina nuda* in the zonal scheme proposed by Banner and Blow[8]? is bad taxonomic practice and the specific names do not appear to satisfy Article 13 of the International Code of Zoological Nomenclature.

One further point of criticism concerns the persistent placing by Banner and Blow of the *G. ampliapertura* and *G. opima* zones (or their now revised equivalent) in their so-called Miocene[8]. This is an integral part of the hypothesis of Eames, Banner, Blow and Clarke[16] that the "Oligocene" is missing in many parts of the world. The published evidence to the contrary and the opinion of most other workers is that the *G. ampliapertura* zone and part, if not the whole, of the succeeding *G. opima* zone form part of the Oligocene[17–20].

One of the best methods of appraisal of a new stratigraphic zonal subdivision is its usage and acceptance by other workers of the same discipline. Bolli's Trinidad zones have some drawbacks, as I have already noted elsewhere[21], but the zones have been workable units in the tropical areas. Berggren[22] made the following comment on Bolli's[1] Paleocene–lower Eocene zones: "This zonation has since (1957) found widespread utility and has served as a standard reference in the recognition of zones based on other pelagic groups, such as the nannoplankton". There is therefore considerable doubt in my mind as to the value and need for such a drastic change of Bolli's zonal scheme as that recently presented by Banner and Blow[8].

METALLURGY

Fatigue—Generation of Vacancies

RECENTLY, it was reported that fatiguing (cyclic straining) at room temperature results in observable diffusion of silver into copper at that temperature[1]. This important effect was attributed to the athermal generation and the subsequent diffusion of vacancies which are greatly in excess of equilibrium.

We report here some preliminary results which are in agreement with the conclusions of Derrick Jones and Dover[1]: that large numbers of vacancies are generated by fatigue, and these vacancies can contribute to diffusive processes.

In the present instance, a precipitation reaction was used to study the influence of large numbers of vacancies. It is known that Guinier–Preston zones (clusters rich in solute) form at ambient temperatures at high rates owing to the supersaturation of vacancies which become frozen-in during the quench from the solution temperature[2]. The zones may be redissolved by heating above the ageing temperature for a short time—yet still within the two-phase region. This treatment is termed "reversion", and on recooling to the original ageing temperature, the zones form at a much lower rate owing to the smaller supersaturation of vacancies which are retained from the lower reversion temperature. In the experiments reported here, specimens in the reverted condition were cyclically strained and then aged.

Aluminium–4 wt. per cent copper was used. The treatment involved first quenching from 540° C to water, followed by ageing for 1 day at 30° C, then reverting at 200° C for 10 min, followed by acetone quenching. After the reversion treatment the specimens were mounted in a specially designed testing device and cycled at the temperature of liquid nitrogen[3]. The specimens were then

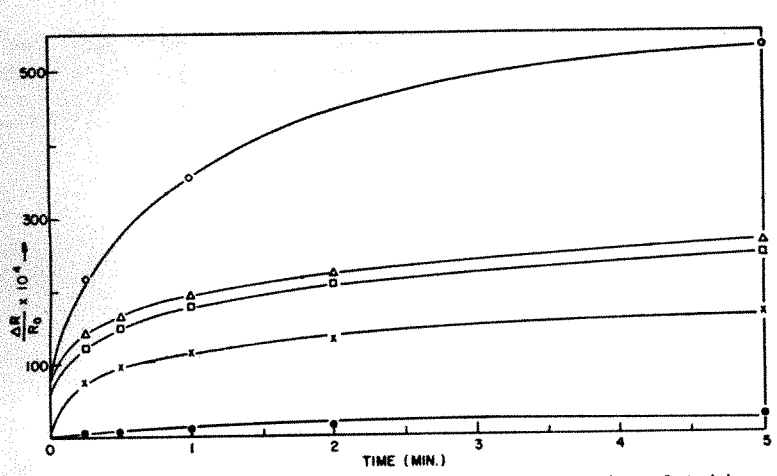

Fig. 1. Ageing curves at 30° C after quenching, reversion, and reversion and straining for various numbers of cycles (see text). ○, As quenched; ×, 10^2 cycles; □, 10^3 cycles; △, 10^4 cycles; ●, as reverted

re-aged at 30° C, and the electrical resistance determined in liquid nitrogen by means of an interruption technique.

The results for strain cycles of 0, 100, 1,000 and 10,000 are shown in Fig. 1. The maximum strain amplitude was ±0·0020 in./in. Data for the isothermal ageing of cyclically strained specimens are clearly representative of accelerated rates of zone formation—the rate increases with the number of cycles. It should be noted that the resistivity always initially increases during the formation of Guinier–Preston zones in this system[2].

We conclude that vacancies must be generated by cyclic straining of the reverted alloy and that these defects are able to contribute to diffusive processes, thus significantly aiding the transport of solute atoms to zones. An estimate of the excess vacancies (C_v) generated by cyclic straining can be obtained by applying the empirical relation of Seitz[4]: $C_v = 10^{-4}\varepsilon$, where ε is the total plastic strain. For 1,000 cycles, the atom fraction of vacancies thus obtained is of the order of 10^{-5}. This number is close to what would be expected for quenching from 500° C; however, it is certain that, before it is strained, the reverted alloy contains less than 10^{-8} atom fraction of vacancies[3].

Room Temperature Stress Corrosion Cracking of Titanium Alloys

IT has been known for more than 10 years that titanium alloys suffer from intergranular stress corrosion cracking if they are in contact with chlorides at elevated temperatures (> 250° C), but it was only 18 months ago that Brown[1] discovered that stress corrosion failures could occur at room temperature in a 3 per cent solution of sodium chloride. Titanium alloys are highly resistant to pitting attack in chloride solutions, and in order to investigate crack propagation rather than crack initiation, Brown used specimens of titanium alloy in the form of notched rectangular bars which had been fatigued in air until fine cracks had formed at the base of the notch. He found with static load tests that under plain strain conditions a 3 per cent solution of sodium chloride caused a decrease in the resistance of the alloy to the further propagation of the crack. This was a very important result, as it indicated that the stress corrosion resistance of titanium alloys under marine conditions depended on the resistance of the surface oxide on the alloy to the solution and not on the intrinsic resistance of the alloy lattice to the propagation of a stress corrosion crack which is the only really safe criterion.

The situation is far more serious than suggested by the experiments of Brown, as we have recently found that stress corrosion cracking of a single phase α-titanium alloy (Ti-5Al-2·5 Sn) in 3 per cent solutions of sodium chloride does not require fine surface notches or fatigue cracks, and it can occur readily on flat chemically polished sheet specimens at room temperature.

By examining thin foils of the alloy by transmission electron microscopy, we had previously shown[2] that hydrides were formed in the alloy surface when the alloy was plastically deformed while immersed in a 3 per cent solution of sodium chloride. This occurred only in susceptible alloys and only in the specific cracking environment, and on the basis of these observations and other data we believe that hydride formation is part of the cracking mechanism. We had also found that at some stage during the chemical polishing of susceptible titanium alloys in a mixture of 40 per cent hydrogen fluoride and 72 per cent nitric acid in the volumetric ratio 2 : 3 the alloy surface became contaminated with hydrides. We therefore tested chemically polished Ti-5Al-2·5 Sn alloy by bending sheet specimens into a curved shape while immersed in a 3 per cent solution of sodium chloride acidified with hydrochloric acid to *p*H 0·75 and then clamping them. Within 6 weeks the specimens developed transgranular cracks on the outer surface of the bend. Specimens that were not chemically polished still show no signs of cracking even after exposure for 3 months.

We shall report on the mechanism of cracking and the crystallographic features of hydride precipitation on a later occasion. The purpose of this communication is to report that pre-existing notches are not required for stress corrosion cracking to occur in titanium alloys, and also to direct attention to the importance of surface preparation in determining susceptibility. The implications of these two points are important both in the determination of the cracking mechanism and in the future use of titanium alloys in marine engineering.

CHEMISTRY

Pseudorutile—a New Mineral Intermediate between Ilmenite and Rutile in the N Alteration of Ilmenite

ALTERATION of the mineral ilmenite, $FeO{\cdot}TiO_2$ in nature involves the processes of oxidation and leaching whereby iron is progressively removed to give a residual product, essentially TiO_2. Several investigations have been reported of the alteration products of ilmenite, but apart from composites of known oxides of iron and titan-

ium, no distinct intermediate phase has been discovered. As a result of an investigation of several altered ilmenite concentrates by X-ray techniques hitherto not applied to this problem, a new crystalline phase has been identified as a major constituent of altered ilmenite. The new phase crystallizes in a disordered structure of hexagonal symmetry and has the theoretical composition $Fe_2O_3 \cdot 3TiO_2$. We propose the name 'pseudorutile' for this new mineral.

The samples used were all commercially available titanium mineral concentrates classed as 'Ilmenite', but are in fact largely composed of alteration products of the mineral ilmenite. (These materials are described at length separately[1].) Chemical and structural analyses of bulk samples used are given in Table 1. Water and oxides other than those of iron and titanium are omitted. The structural composition was derived from powder diffraction data subsequent to the identification of pseudorutile.

Table 1. CHEMICAL AND STRUCTURAL COMPOSITION OF ALTERED ILMENITE SAMPLES FROM VARIOUS LOCALITIES

Sample	Chemical composition in weight per cent			Estimated concentration of crystalline phases		
	FeO	Fe_2O_3	TiO_2	Ilmenite	Pseudorutile	Rutile
Florida ilmenite	4·1	25·2	64·2	Trace	High	Low
New Jersey ilmenite	0·1	32·2	62·7	Trace	High	Low
Quilon (Indian) ilmenite	9·4	25·4	60·0	Medium	High	Low
Brazilian ilmenite	5·7	31·5	57·1	Low	High	Low

Rotation of single grains of altered ilmenite about arbitrary axes in initial X-ray diffraction studies produced patterns characteristic of single crystals rather than of polycrystalline samples. Consequently, we treated small mineral grains of altered ilmenite like single crystals and recorded the diffraction patterns representing different orientations with rotating crystal, equi-inclination Weissenberg and precession camera techniques. Zirconium-filtered molybdenum $K\alpha$ radiation was used.

From these patterns it was determined that the major portion of the grains consisted of hexagonal pseudorutile with $a = 2{\cdot}872$ Å and $c = 4{\cdot}594$ Å, using the dimensions of rutile as an internal standard. Small amounts of rutile with $a = 4{\cdot}594$ Å and $c = 2{\cdot}958$ Å were present in all grains in a specific threefold orientation. Rhombohedral ilmenite with the hexagonal dimensions $a = 5{\cdot}078$ Å and $c = 14{\cdot}135$ Å was occasionally observed. The orientation relationship between ilmenite, pseudorutile and rutile is shown in Fig. 1.

In addition to sharp and well-defined diffraction spots present on all photographs, a number of diffuse streaks of considerable intensity were observed on $l = 2n + 1$ level photographs of pseudorutile. These streaks are caused by the disordered structure of pseudorutile and do not originate from another phase.

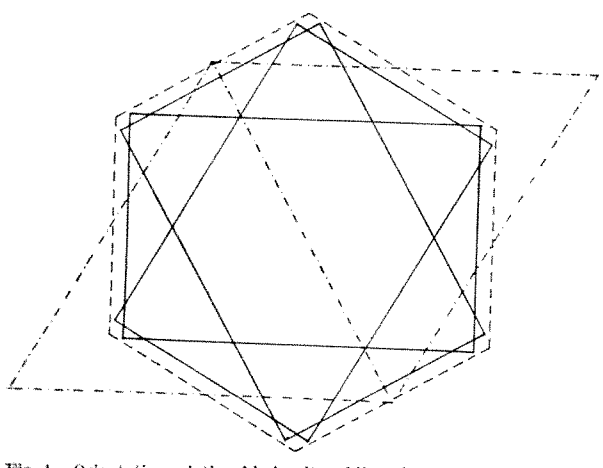

Fig. 1. Orientation relationship in altered ilmenite. ———, Ilmenite; — — — —, pseudorutile; ————, rutile triplet

The positions and thermal parameters of the atoms in pseudorutile were derived from diffraction data recorded by the Weissenberg technique and were refined by least-squares analysis. The best agreement between observed and calculated structure factors ($R = 4{\cdot}5$ per cent) was found with the oxygen atoms placed in a close-packed hexagonal arrangement. A fraction of the octahedral sites available in such a structure is statistically occupied with iron and titanium atoms according to the stoichiometry $Fe_2Ti_3O_9$.

The disordered structure of pseudorutile can be described as a transition phase between the atomic arrangements in ilmenite and rutile in which the nearly perfect close-packed hexagonal arrangement of oxygen atoms is but little affected during the transformation ilmenite → pseudorutile → rutile. The structural relationship between all three phases is apparent in the orientation relationship illustrated in Fig. 1.

The alteration of ilmenite can be formulated as a topochemical reaction in which the number and arrangement of oxygen atoms in ilmenite are essentially preserved in pseudorutile and rutile:

$$\underset{\text{Ilmenite}}{Fe^{II}Ti_3O_9} \xrightarrow{\text{Oxidation}} \underset{\text{Pseudorutile}}{Fe^{III}_2Ti_3O_9} + 1/2Fe^{III}_2O_3$$

Further removal of Fe_2O_3 from pseudorutile causes the direct formation of rutile without formation of other crystalline phases. Pseudobrookite and rutile are formed by heating pseudorutile to temperatures above 800° C:

$$\underset{\text{Pseudorutile}}{Fe^{III}_2Ti_3O_9} \xrightarrow{>800^\circ\,C} \underset{\text{Pseudobrookite}}{Fe^{III}_2TiO_5} + \underset{\text{Rutile}}{2TiO_2}$$

Two minerals of the composition $Fe_2Ti_3O_9$ have been reported: arizonite[2,3] and proarizonite[4]. In neither case are the published interplanar spacings and intensities identical with those of pseudorutile. With samples having a high rutile/pseudorutile ratio, the superposition of most of the powder lines might result in the presence of pseudorutile being overlooked—or mistaken for rutile.

Mechanism of the Acid Hydrolysis of Pentammine Cobalt Complex Ions

UNEQUIVOCAL evidence in support of a particular mechanism for the acid hydrolysis reaction (1) has not, as yet, been obtained.

$$[Co(NH_3)_5X^{2+}] + H_2O \rightleftarrows [Co(NH_3)_5H_2O^{3+}] + X^- \quad (1)$$

$$(X = F^-, Cl^-, Br^-, I^-, NO_3^-, H_2PO_4^-)$$

Several recent communications[1-4] serve to emphasize that the problem is still an open issue. In any kinetic investigation a knowledge of the species present is of prime importance, particularly, in a reaction of type (1), where ion-pairs are likely to occur; the acceleration of reaction (1) by added anions has been observed[5,6]. In a recent detailed investigation for ($X = Cl^-$), Laurie and Monk[7] attributed these accelerations to ion-pairs being more reactive than the free complex ion; the thermodynamic dissociation constants derived from the rate data for the proposed ion-pairs were in good agreement with values from investigations of the electromotive force[8]. The results are collected in Table 1. It is the purpose of this communication to show the importance of these results with regard to two misconceptions and to the mechanism of reaction (1).

According to Basolo and Pearson[9], increased reaction rates in the presence of added anions cannot be attributed solely to more reactive ion-pairs. Their conclusion is made invalid by the above results and by the findings of Davies[10] on other similar reactions. Moreover, Basolo[11] takes the increase in hydrolysis rate with decrease in positive charge on the complex to be indicative of an S_N1 reaction; for example, for similar low-spin d^6 complexes the decrease in reactivity follows the order Fe(II) > Co(III) > Pt(IV), but in such a sequence differences in ligand field strength will also be operative. For the species $[Co(NH_3)_5Cl]^{2+}$, $[Co(NH_3)_5Cl]L^+$, and $[Co(NH_3)_5Cl]M^0$, where L^- and M^{2-} are ion-pairing anions, ligand field strength differences are negligible and the observed[7] increase in hydrolysis rate along the series may be attributed solely to the lowering of the positive charge. These rate increases (Table 1) are, however, small (the activation energy changes by only 0·1 kcal on lowering the charge from +2 to 0) and can be interpreted in terms of an S_N2 mechanism in which the lowering of the positive charge promotes the removal of the chloride ligand (ion–ion interaction) but discourages attack by the nucleophilic water molecule (ion–dipole interaction). The former effect, being the greater, would predominate, giving the observed increases and at the same time preserving the well-established "bond breaking more important than bond making" order.

Table 1*

Ligand	Nitrate	Glycollate	Sulphate	Malonate	Phthalate
k_2/k_1	1·1	1·15	2·05	2·13†	2·95
K	0·09	0·03$_5$	0·0032	0·0050	0·0030

* Data taken from ref. 7.
† Incorrectly given as 2·08 in ref. 7. k_2/k_1 is the ratio of the reaction rate constant of the ion-pair to that of the free complex ion, at 35°. K is the thermodynamic dissociation constant at 35° C.

Langford's analysis[3] of the free-energy data suggests that for an S_N1 mechanism to occur the entering nucleophile must be previously present in the second co-ordination sphere of the Co(III) ion. If this is so, then the non-entry of the ion-pairing anion into the first co-ordination sphere must rule out an S_N1 process. By similar reasoning an S_N2-trans mechanism can be discounted.

The data presented comply with an S_N2-*cis*-type mechanism, in which the transition state involves an extended Co—X bond and an adjacent weak bond between the cobalt-atom and a water molecule present in the second co-ordination sphere, the reaction being completed by the breaking of the Co—X bond and the simultaneous entering of the water molecule. The inclusion of the extended Co—X bond is in accordance with Vlcek's deductions[12] from polarography measurements and means that expansion of the inner co-ordination sphere is not necessary. For minimum potential energy the ion-pairing anion must be "*trans*" to the departing ligand and hence would not be expected to enter the inner-co-ordination sphere on the basis of this mechanism. The proposed mechanism also fits in well with other observations on deuteration[13] and steric hindrance[14] effects and the findings that complexes of the type *cis*-$[Co(en)_2XCl^+]$, $X = NCS^-$, N_3^-, and NO_2^-, hydrolyse without stereochemical change[15].

Finally, it is to be noted that the mechanism proposed above is very similar to the "solvent-assisted dissociation" process favoured by others (for example, see ref. 2). Indeed, the difference may be one of semantics only.

Enzymatic Etching of Single Crystals of Naphthalene

IT was previously observed[1] that when crystals of naphthalene, which had been grown from the vapour phase, were immersed in an aqueous suspension of soil pseudomonads for about 10 min at room temperatures, a small number (about 10^2 cm^{-2}) of well-defined, pyramidal pits were produced on the principal habit faces {00*l*}. This result was tentatively interpreted to mean that preferential attack of the naphthalene by the pseudomonads occurred at the regions of emergence of dislocations, a view which was consonant with: (i) the conclusions of Kochendorfer[2], who indicated that dislocations lying in {010} planes, having a Burgers vector in the [001] direction, might be possible in naphthalene; (ii) the results of Koslovskii[3], who observed growth spirals on the {00*l*} faces of certain naphthalene crystals; (iii) the more recent work of Sears[4], who also proffered evidence for dislocations emergent at {00*l*} faces. The result agreed

with the molecular interpretation of Davies and Evans[5] concerning the oxidative metabolism of naphthalene by microbial enzymes.

This communication reports some of the salient features of a more rigorous investigation which we have made of the enzymatic attack of naphthalene crystals produced in two distinct ways. Type I single crystals of 'scintillation grade' naphthalene were grown from the melt using the Bridgman technique by Thorn Electronics, Ltd. (Surbiton, Surrey). Type II single crystals were produced by slow sublimation of polycrystalline 'molecular weight grade' naphthalene. The etchant used consisted of an aqueous solution of the cell-free enzyme derived from pseudomonads as follows. Cells grown in a naphthalene–mineral salts medium under forced aeration were sonically disrupted in a phosphate buffer of *p*H 7 (0·05 M) to yield a supernatant (after centrifuging at 25,000*g*) which was active on naphthalene in the presence of reduced niacin adenine dinucleotide (NAD) as cofactor. Etch patterns on the {00*l*} faces only could be studied by transmission optical microscopy—a restriction imposed largely by the cleavage behaviour of naphthalene crystals.

In Fig. 1, which shows a {00*l*} face of a type I crystal after etching for 30 sec, there are numerous flat-bottomed etch-pits which tend to be hexagonal in outline and all of which are of the same crystallographic orientation. Fig. 2 is an enlargement of part of the surface shown in Fig. 1: the tendency for hexagonal etch-pits to be produced is more evident here. Type II crystals behave in essentially the same way, although there does appear to be rather more aptitude for triangular (flat-bottomed) pits to be produced than with type I crystals.

We are of the opinion that it is unlikely, but not impossible, that the etch-pits in Figs. 1 and 2 are nucleated at the termini of dislocations that glide in {0*l*0} planes (and would emerge at {00*l*} faces). (Gordon[6] has recently shown

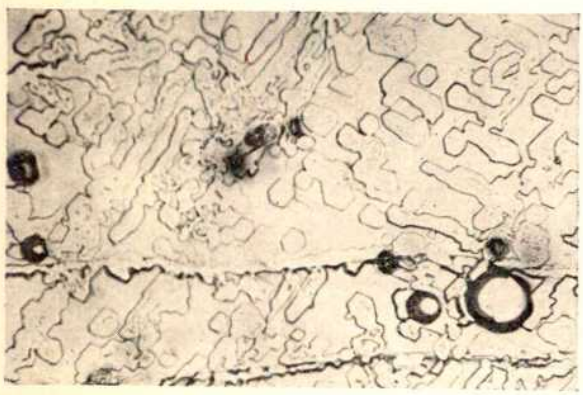

Fig. 1. Etch pattern on 00*l* face of naphthalene crystal after 30 sec exposure to enzymatic etchant (× *c*. 103)

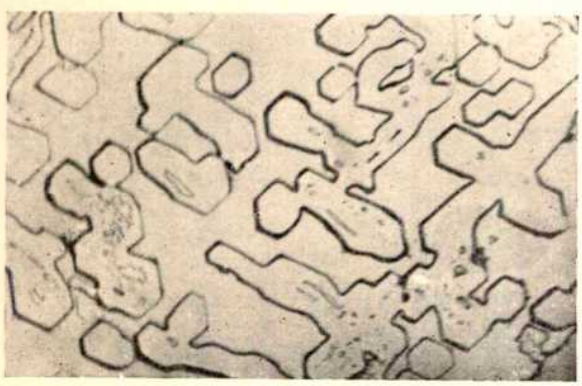

Fig. 2. Magnified area of another region of the crystal face shown in Fig. 1 (× *c*. 206)

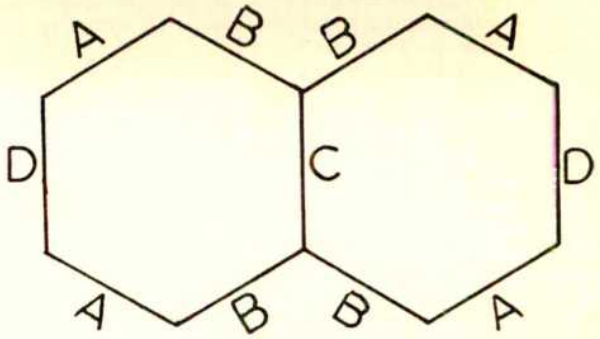

Fig. 3. The various bond types in naphthalene

that there is a greater likelihood for dislocations in naphthalene to glide in {00*l*} rather than in {010} planes.) We feel that they are more likely to be undersaturation etch-pits[7] which have been nucleated randomly on the {00*l*} faces. So far as the crystallographic orientation of the pits is concerned, it is possible to explain the results obtained with both types of crystals in terms of the anisotropy of reaction rates at various crystallographic planes of the naphthalene lattice. This anisotropy, in turn, devolves on differences of reactivity at various sites in the naphthalene molecule. In essence, our conclusions are that bonds *A* and *B* (see Fig. 3) are more susceptible to attack by pseudomonads than bonds *C* and *D*. A full account of this work is to be published elsewhere.

We wish to acknowledge the encouragement and advice of Prof. S. Peat.

Dimethylalloxazine as an Electron Donor and Acceptor

I WISH to report that 1,3-dimethylalloxazine (I) can form molecular complexes acting not only as an electron acceptor but also as a donor. It was possible to crystallize complexes from ethylene dichloride with the following compounds: pyrene, tetracyanoethylene (TCNE), and 2,3-dichloro-5,6-dicyano-*p*-benzoquinone. The results of the elemental analysis indicate that these complexes contain dimethylalloxazine and the other component in a ratio of 2 : 1 regardless of whether the latter is a donor or acceptor. As the infra-red spectra of the complexes are very close to the superimposed spectra of the components,

I

there is no appreciable change in the intramolecular bonds by complex formation. Therefore, the ground states of the complexes are essentially non-bonding. The complexes are more deeply coloured than the components. For example, the pyrene and TCNE complexes are deep yellow. On the other hand, dimethylalloxazine is pale yellow and the other two components are colourless. As shown in Fig. 1, the appearance of a new absorption is clearly seen in these complexes. It can be concluded that these complexes are of the charge transfer type; dimethylalloxazine in the pyrene complex is acting as an electron acceptor and in the TCNE complex as a donor.

In the present complexes, which have essentially non-bonding ground states, the energies of the molecular orbitals may be little different from those in the separate components. In a naïve approach, the energy of the first charge transfer band in a given complex can be considered as the energy difference between the highest occupied molecular orbital of the donor and the lowest vacant molecular orbital of the acceptor[1]. Therefore, the relative positions of the molecular orbitals associated with the complex formation can be ascribed on the basis of the energies of the excitation within the component molecules and of the first charge transfer bands in the complexes. Strong donors are expected to have their highest occupied molecular orbitals at relatively high energies and strong acceptors are expected to have their lowest vacant molecular orbitals at relatively low energies.

In Fig. 2, the lowest vacant molecular orbitals of the acceptors, including dimethylalloxazine, were located relative to the highest occupied molecular orbital of pyrene by means of the energies of the charge transfer bands in the pyrene complexes. The positions of the remaining molecular orbitals were assigned on the basis of the first excitation energies in the component molecules. As any changes in energy of the molecular orbitals in forming the complex have been ignored, the present position is only approximate. Nevertheless, it is clearly shown that the highest occupied molecular orbital of dimethylalloxazine is located between those of the donor and the acceptors, and the lowest vacant molecular orbital of the alloxazine is located again between those of the donor and acceptors. In agreement with the observation reported here, the molecular orbital diagrams given in Fig. 2 indicate that dimethylalloxazine can be an electron donor when combined with strong acceptors and can be an acceptor when combined with strong donors.

Polymorphic Forms of the Diaminopyrene-*p*-chloranil and Related Molecular Complexes

I REPORTED earlier that most of the quinone complexes with electrical resistivities of 10^8 ohm cm or less have essentially dative ground states[1]. The only exceptions found were the 1,6-diaminopyrene complexes with *p*-chloranil and *p*-bromanil. It therefore seemed worthwhile to examine these complexes further. The resistivity values reported for the *p*-chloranil complex are scattered in a wide range, namely 10^3–10^4 ohm cm for the pressed polycrystalline samples[2,3] and 10^5–10^9 ohm cm in the three directions of the single crystal[4]. This communication reports the existence of some polymorphic forms of the 1,6-diaminopyrene-*p*-chloranil and related molecular complexes. The polymorphic forms are distinctly different in colour, diffuse reflectance spectrum, vibrational spectrum, X-ray diffraction, and also electrical resistivity. The scattered resistivity values appear to be well related to those of such forms.

The *p*-chloranil complex prepared in chloroform, the solvent from which Kronick and Labes grew their single crystal[4], is dark blue and green when pulverized. The composition is 1 : 1. Calculated (per cent): carbon 55·3, hydrogen, 2·5; nitrogen, 5·9; chlorine, 29·7. Found (per cent): carbon, 55·2; hydrogen, 2·4; nitrogen, 6·1; chlorine, 29·4. The diffuse reflectance spectrum shown in Fig. 1 indicates that, although the spectrum has an absorption minimum at about 530 mμ, the absorption extends to about 1·8 μ. The pressed pellet exhibits a resistivity of the order of 10^7 ohm cm. This value seems to be reasonable as the average for 10^5–10^9 ohm cm observed in the three directions of the single crystal. This green form can be transformed into the brown form (mentioned later) by recrystallization from benzene.

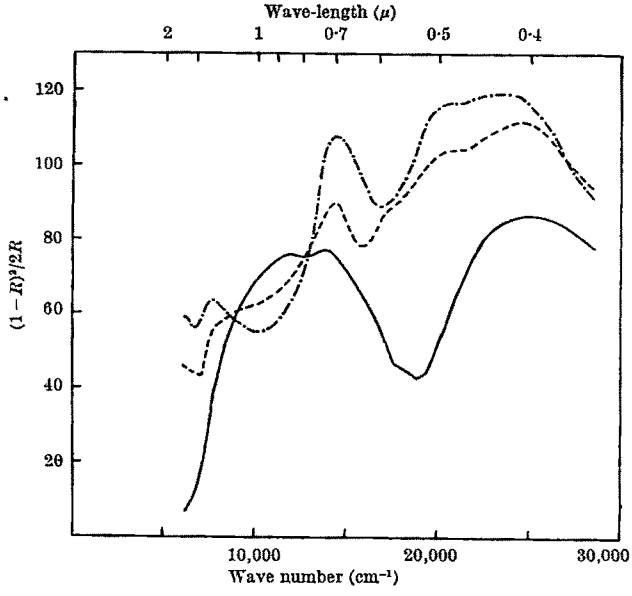

Fig. 1. Kubelka-Munk plots of diffuse reflectance spectra of diaminopyrene-*p*-chloranil complex, green (——), brown (- - -), and low-resistivity (— · — · —) forms

When benzene is used for the preparation, the brown form crystallizes. The composition is again 1 : 1. Found (per cent): carbon, 55·2; hydrogen, 2·8; nitrogen, 5·9; chlorine, 29·2. The resistivity of the pressed pellet prepared after careful drying of the sample is of the order of 10^5 ohm cm. This brown form can easily be transformed into a third form, exhibiting a resistivity of only a few ohm cm, by compression in the presence of benzene. Even a trace of the solvent remaining in the sample can result in a lowering of the resistivity of the pellet to about 10^3–10^4 ohm cm. It should be noted that the second and third forms show electronic absorption covering the visible and infra-red regions and extending beyond 2·5μ. The large difference in the optical and electrical properties found in these polymorphic forms shows the importance of the stacking of the component molecules as one of the factors determining the electronic properties of such a complex.

The vibrational spectra of the green and brown forms of the *p*-chloranil complex are similar to the superposed spectra of the components. Therefore, they appear to have essentially non-bonding ground states. However, the patterns in the region between 5·5 and 6·8μ are very characteristic of each form, and this indicates that the mode of intermolecular interaction is different in these forms (see Fig. 2*a* and 2*b*). The whole spectrum of the brown form was presented with those of the components in my previous note[1]. The spectrum of the low resistivity form is very dark, suggesting that the electronic absorption seen in Fig. 1 extends over the entire sodium chloride region. Although the vibrational bands of the various components are for the most preserved, their intensities are very much modified. Furthermore, the carbonyl stretching vibration band is shifted to longer wave-lengths by about 0·2 μ or 50 cm^{-1} in this form. This unusually large shift may indicate that the crystal structure is favourable for a strong interaction between the component molecules and that the contribution of the dative structure to the ground state is appreciable. It is suggested that the low resistivity form of the *p*-chloranil complex is near the border line between complexes with non-bonding ground states and those with dative ground states.

Green and brown forms were also found for the trichloromonobromo- and dichlorodibromo-*p*-benzoquinone complexes. The green forms, prepared in chloroform, would seem to be similar to the green form of the *p*-chloranil complex. On the other hand, the brown forms, crystallized from benzene, show infra-red spectra quite different from that of the brown form of the *p*-chloranil complex. Figs. 2*d* and 2*e* show, respectively, the spectra of the green and brown forms of the 2,5-dichloro-3,6-dibromo-*p*-benzoquinone complex.

Only the brown form is obtainable both from chloroform and from benzene for the monochlorotribromo-*p*-benzoquinone and *p*-bromanil complexes. All the brown complexes except the brown form of the *p*-chloranil complex are of similar nature and exhibit resistivities of the order of 10^3 ohm cm. This value is in accordance with that reported for the *p*-bromanil complex by Labes *et al.*[2].

Transition State in the Inversion of the Sachse Hexagon

A FEW years ago, Hendrickson[1] suggested that the transition state in the inversion of the chair form of the Sachse hexagon in *cyclo*hexane was one in which half the molecule is in the planar Baeyer form and the other half in the Sachse chair form. This suggestion has recently been accepted by Anderson[2]. However, for various reasons, it is difficult to accept this idea.

For one thing, the two halves do not fit each other. The squared distances between opposite sides are, in the Baeyer and in the Sachse hexagons $2a^2(3/2)$ and $2a^2(4/3)$, respectively, and the squared distances between opposite corners $(36/9)a^2$ and $(33/9)a^2$, respectively, where a is the carbon–carbon distance. Secondly, there is nothing to prevent us from imagining forms of the carbon hexagon intermediate between the Baeyer and Sachse models, in which the angles are different and the partition of strain therefore more or less skew, as it is to an extreme degree in Hendrickson's model. But it is very questionable whether such non-symmetric structures can be formed from the highly symmetrical Sachse hexagon by stress-

ing forces from isotropic surroundings: and finally, if the partition of strain is skew, the internal molecular forces cannot balance each other, as they must.

So it is difficult to escape the conclusion that all six angles are equal in the strained hexagons, and that the transition state in question therefore must be the Baeyer form of *cyclo*hexane. In this form, the potential energy arises partly from the six angular strains and partly from the twisting of six pairs of valency triads from staggered into eclipsed orientations. In principle, it should thus be possible to calculate the work necessary to bring the *cyclo*hexane molecule from its normal strainless state into the transition state. The work of twisting has been determined by Pitzer[3] at about 2·8 kcals or about 12 kJ for each "mole" of a pair. The contribution from the work of twisting may therefore be estimated at about 72 kJ. The work, V, of extending each of the six angles from the tetrahedric value to 120° may be calculated from

$$2V = A\alpha^2$$

where A is the angular restoring force, and α the angular difference 10·53° = 0·1838 radian. In a well-known review, Westheimer[4] has accepted $A = 8 \times 10^{-12}$ erg/(radian)^2 for one angle in one molecule, while Wilson[5], on the basis of his investigation of the infra-red and Raman spectra of *cyclo*butane, derived $A = 7{\cdot}67 \times 10^{-12}$ for the same quantity. Westheimer's value yields for one mole

$$6V = 48{\cdot}82 \text{ kJ}$$

The total work of activation may therefore be estimated at about 120 kJ/mole, which means that the inversion of the Sachse chair form should be an extremely slow process at room temperature.

Tentative calculations based on the lowest frequency observed in the Raman spectrum[6,7] of *cyclo*hexane itself lead to an even higher work of activation of the reaction in question. Thus the evidence derived from infra-red and Raman spectra seems to disagree completely with that derived from nuclear magnetic resonance spectra. This situation calls urgently for a revision of the interpretation of both kinds of spectra. For example, one might ask, is the inversion of the Sachse hexagon the only possible explanation of the coalescence of a doublet in the nuclear magnetic resonance spectrum existing at lower temperature into a singlet at room temperatures[2] ? Or could the phenomenon be caused by the "thawing" of a vibration of the hydrogen atoms which is "frozen" at lower temperatures ?

Electronic Transitions in Hexachloro-co-ordinated Titanium and Chromium

IN the crystal structure of α-titanium trichloride[1], the chlorine ions are in a hexagonal close-packed pattern, whereas in γ-titanium trichloride and chromium trichloride the chlorine ions are close-packed in a cubic pattern[1,2]. The metal ions occupy two-thirds of the octahedral holes between alternate layers of chlorine ions.

Wessel and Ydo[3] investigated the crystal structure of the isomorphous compounds $Cs_3Ti_2Cl_9$ and $Cs_3Cr_2Cl_9$. According to their results, units of $Ti_2Cl_9^{3-}$ and $Cr_2Cl_9^{3-}$ are present in the crystal in the form of two octahedra sharing a face.

The similarity of the octahedral surroundings in the compounds of the transition metal ions mentioned above induced us to study the optical transitions of α- and γ-titanium trichloride, $Cs_3Ti_2Cl_9$, chromium trichloride and $Cs_3Cr_2Cl_9$. The optical d–d transitions of transition metal ions placed in a crystal field of a certain symmetry can be interpreted on the basis of an electrostatic model in which the ligands are considered as point charges or point-shaped dipoles. According to the single-electron approximation the five-fold degenerate d-level of a transition metal ion will split into a three-fold degenerate and a two-fold degenerate level if the transition metal ion is placed in a crystal field of ideal octahedral symmetry.

Recently, we made observations of the electronic transitions of α-, β- and γ-titanium trichloride[4]. The spectra of α- and β-titanium trichloride have also been published by Clark[5]. However, our spectrum of α-titanium trichloride, reproduced in Fig. 1, curve 1, does not show the shoulder at 12,000 cm^{-1} observed by Clark.

The spectrum of γ-titanium trichloride is quite analogous, which is to be expected in view of the correspondence of the crystal structures of α- and γ-titanium trichloride. $Cs_3Ti_2Cl_9$ was prepared by fusing in a sealed quartz tube a mixture of caesium chloride and α-titanium trichloride (Stauffer *H.A.*) in the molar ratio of 3 : 2. After the tube had been heated at about 725° C for about 25 h the compound $Cs_3Ti_2Cl_6$ had formed and was identified by X-ray analysis.

In order to avoid contamination by oxygen and water the manipulations were carried out in a glove-box through which dry nitrogen was passed. The reflexion spectra were run by means of a 'Beckman *DK* 2' type spectrophotometer using magnesium oxide as a blank. The reflexion spectrum of $Cs_3Ti_2Cl_9$ is shown in Fig. 1, curve 2. The chromium trichloride used was sublimed chromium trichloride (Riedel-De Haen *A.G.*, Seelze-Hannover). The reflexion spectrum is shown in Fig. 2, curve 1. The complex $Cs_3Cr_2Cl_9$ was prepared and analysed in an analogous way as the complex $Cs_3Ti_2Cl_9$. The reflexion spectrum is given in Fig. 2, curve 2.

The titanium (III) ion has the electron configuration $A(3d)^1$. In ideal octahedral surroundings the $(3d)^1$ level splits in a three-fold degenerate t_{2g} and a two-fold degener-

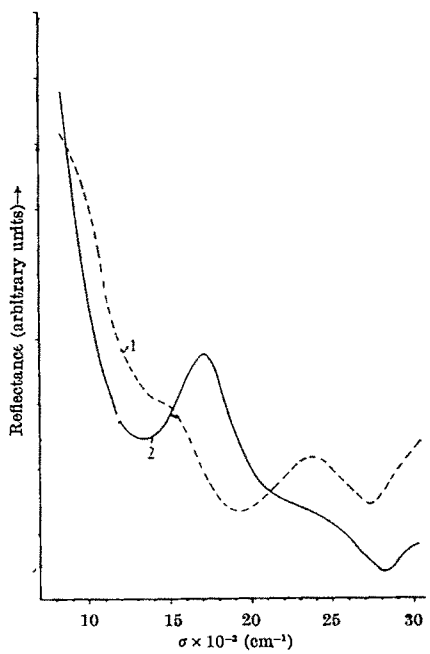

Fig 1. Reflexion spectrum of: 1, α-$TiCl_3$, 2, $Cs_3Ti_2Cl_9$

ate e_g level. From the knowledge of the crystal structure we conclude that in α- and γ-titanium trichloride the titanium ions are octahedrally surrounded by chlorine ions, whereas the deviations from the octahedral symmetry are relatively small. The absorption band at 14,300 cm^{-1} observed for α- and γ-titanium trichloride will correspond consequently to the transition $^2T_{2g} \rightarrow {}^2E_g$[4,5].

One might suggest that the bands observed for α- and γ-titanium trichloride at 14,300 cm^{-1} and 19,300 cm^{-1}, as well as the bands observed for $Cs_3Ti_2Cl_9$ at 13,400 cm^{-1} and 21,500 cm^{-1}, are caused by a splitting of the band formed by the transition $^2T_{2g} \rightarrow {}^2E_g$. The magnitude of such a split, however, seems too large to be caused by the Jahn-Teller effect or by deviations from the octahedral symmetry. Consequently, it would be reasonable to assign the band observed at 19,300 cm^{-1} for α-titanium trichloride and at 21,500 cm^{-1} for $Cs_3Ti_2Cl_9$ to charge-transfer transitions of the type $\pi \rightarrow t_{2g}$.

The chromium (III) ion has the electron configuration $A(3d)^3$. In ideal octahedral surroundings the strong field configuration $(t_{2g})^3$ gives rise to the states $^4A_{2g}$, ^2E_g, $^2T_{1g}$, and $^2T_{2g}$. The excited configuration $(t_{2g})^2(e_g)$ produces a.o. the states $^4T_{2g}$ and $^4T_{1g}$. It appears[6] that the level with $^4T_{2g}$ symmetry is lower in energy than the level with $^4T_{1g}$ symmetry. The only spin-allowed transitions are $^4A_{2g} \rightarrow {}^4T_{2g}$ and $^4A_{2g} \rightarrow {}^4T_{1g}$. The transitions $^4A_{2g} \rightarrow {}^4T_{2g}$ and $^4A_{2g} \rightarrow {}^4T_{1g}$ are observed in $Cr(H_2O)_6^{3+}$ at 17,400 and 24,500 cm^{-1} (ref. 7).

In chromium trichloride and $Cs_3Cr_2Cl_9$, the chromium ions are also octahedrally surrounded by chlorine ions. We therefore assign the bands observed for chromium trichloride at 13,600 cm^{-1} and 18,900 cm^{-1} and the bands observed for $Cs_3Cr_2Cl_9$ at 12,800 cm^{-1} and 18,000 cm^{-1} to the transition $^4A_{2g} \rightarrow {}^4T_{2g}$ and $^4A_{2g} \rightarrow {}^4T_{1g}$ respectively[5].

In Fig. 3 we give a picture of the discussed *d–d* transitions. The wave numbers of maximum absorption are summarized in Tables 1 and 2.

Table 1*

	α,γ-Titanium trichloride	$Cs_3Ti_2Cl_9$
$^2T_{2}\rightarrow{}^2E_g$	14,300	13,400
$\pi\rightarrow t_{2}$	19,300	21,500

Table 2*

	Chromium trichloride	$Cs_3Cr_2Cl_9$
$^4A_{2g}\rightarrow{}^4T_{2g}$	13,600	12,800
$^4A_{2g}\rightarrow{}^4T_{1g}$	18,900	18,000

* Wave numbers in cm^{-1}.

Strengths of *p*-Alkoxy- and -Alkylthio-benzoic Acids

ALTHOUGH the literature contains references to the pK_a values of the acids (I)[1–3] and (II)[4], in neither case have they been determined in a common solvent; in each series, the group R has included only primary and secondary alkyl. Moreover, a discrepancy exists between the results of Jones and Speakman[1] and of Cavill, Gibson and Nyholm[2] for the *p*-alkoxybenzoic acids (I; R= Me, Et and Pr^i).

(I)

(II)

The apparent pK_a values for the acids (I) and (II), where R is Me, Et, Pr^i and Bu^t, respectively, and for benzoic acid, have been determined by potentiometric titration in 30 per cent v/v acetone–water. The choice of this solvent system was dictated largely by the lower solubilities of the acids (II) compared with those of (I).

Each alkoxybenzoic acid (I) is weaker than its alkylthio analogue (II); this is consistent with the more limited data of Baker, Barrett and Tweed[3]. Relative to benzoic acid, the variation in acid strength with variation in

R is for (I), Benzoic > Bu^t > Me ≳ Et > Pr^i, and for (II), Bu^t > Pr^i > Benzoic > Et ≳ Me. These trends confirm those observed by Cavill, Gibson and Nyholm[2] for (I; R=Me, Et, and Pr^i), and by Baliah, Shanmüganathan and Varadachari[4] for (II; R=Me, Et, Pr^i). The position of the Bu^t acid in each case is a clear demonstration of the operation of a steric effect involving the Bu^t group and the *o*-hydrogen atoms, which prevents the attainment of coplanarity of the bonds of the oxygen (or sulphur) atom and the benzene ring, and thereby destabilizes the acid relative to its anion. It would appear that a small, though real, steric effect operates in (II) even when R is Pr^i. The steric interactions present in (II; R=Pr^i and Bu^t, respectively) would appear to be so effective as to hinder the operation of the electron-releasing mesomeric effect of the sulphur atom to such a degree that the electron-withdrawing inductive effect of this atom becomes predominant in determining the free-energy difference between each of these acids and its anion.

A more complete interpretation must await the outcome of investigations into the esters of (I) and (II), and the corresponding *m*-alkoxy- and alkylthio-benzoic acids, and their esters.

BIOCHEMISTRY

Incorporation of Histamine Ribonucleoside into Soluble Proteins

ISOTOPICALLY labelled histamine ribonucleoside can be detected in the urine of experimental animals after intraperitoneal administration of either 2(ring)-^{14}C-labelled histamine[1], or similarly labelled histamine-adenine-dinucleotides[2]. However, in such experiments the quantities of histamine ribonucleoside recovered from the urine represent only a small percentage of the expected amount. This apparent disappearance of histamine ribonucleoside *in vivo* suggested the possibility of its combination with proteins. The incorporation of amines into proteins, probably through transamidation, was studied by Waelsch *et al.*[3,4]. A similar system, that is, a 100,000*g* supernatant of a guinea-pig liver homogenate[3], was used in our investigations. Histamine ribonucleoside was prepared from histamine adenine dinucleotide phosphate[5], as already described[2]. The degree of purity of this material was checked ionophoretically[1,2], and only a single spot was observed in either *tris*-hydrochloric acid (*p*H 8·0) or sodium borate (*p*H 9·1). As shown in Table 1, there was appreciable incorporation of radioactivity into the acid insoluble fraction of the incubation mixtures when either histamine, or histamine ribonucleoside, or histamine-adenine-dinucleotide-phosphate was used. This incorporation was Ca^{2+}-dependent. Thus, in controls from which Ca^{2+} was omitted, very few scintillations were counted, and radioactivity approached background values (Table 1). When tested under conditions similar to those in Table 1, the guinea-pig liver supernatant used in our investigations was found free of activities capable of liberating inorganic phosphate from the dinucleotide. This may be partly due to the lack of the proper enzymes (that is, pyrophosphatases and phosphatases) and partly because of the lack of magnesium ions. In any event, this finding led us to the conclusion that the dinucleotide was probably attached as such on the protein molecule.

Table 1 INCORPORATION OF 2(RING)-^{14}C-LABELLED HISTAMINE AND CERTAIN OF ITS N(RING)-RIBOSYL DERIVATIVES IN THE ACID-INSOLUBLE FRACTION OF GUINEA-PIG LIVER PREPARATIONS

Compound	Ca^{++} (5 mM)	Radioactivity above background (d.p.m. per 2·7 mg of protein)
Histamine	+	5,688
Histamine	−	35
Histamine ribonucleoside	+	1,494
Histamine ribonucleoside	−	32
Histamine-adenine dinucleotide phosphate	+	1,840
Histamine-adenine dinucleotide phosphate	−	26

All compounds were identically labelled. Each amine (0·25 M, 50,000 d.p.m.) was incubated for 1 h at 37° C with an equal portion of 100,000*g* supernatant of a guinea-pig liver homogenate (ref. 3) corresponding to 2·7 mg of protein, as determined by the biuret method (ref. 8), in a total volume of 2·0 ml. The reaction was stopped by adding, in the cold, trichloroacetic acid to 5 per cent final concentration. The mixture was centrifuged and the supernatant was discarded. The precipitate was redissolved in 1·0 ml. of 0·2 N sodium hydroxide and reprecipitated with 3 ml. of 15 per cent trichloroacetic acid, in the cold. This operation was repeated five times. Finally, the washed precipitate was dissolved in 1·5 ml. of 'Hyamine' (Packard Instrument Co., Inc.) and the sample was prepared for counting in the scintillation counter as before (ref. 9). After counting, an appropriate quantity of ^{14}C-labeled toluene was added to the sample (internal standard) and counting was repeated. The efficiency of counting was computed from the difference of the two counts, and on this basis the results were converted to disintegrations per minute (d.p.m.). The background counts were about 30 c.p.m.

In the experiments shown in Table 1, incorporation of radioactivity into proteins from free histamine was greater than from its ribonucleoside derivatives. However, unlike histamine and other amines (see, for example, ref. 6), histamine ribonucleoside is not deaminated in mammalian tissues[1,2,7,10]. Because deaminated compounds would not react in the transamidation system, it follows that the histamine dinucleotides and histamine ribonucleoside would probably have a greater chance than histamine of becoming attached on to proteins if found in the proper *in vivo* environment (that is, in the presence of deaminases). These preliminary observations explain qualitatively previously found quantitative discrepancies and open the route for further experimentation concerning the significance of the formation and fate of histamine dinucleotides *in vivo*.

Release of Peptide Chains from Rat-liver Polysomes by the *N*,*N*-Dimethyl-*p*-methoxy-L-phenylalanyl Analogue of Puromycin

THE synthesis of a peptide on the surface of a ribosome takes place in the presence of messenger RNA, aminoacyl-*s*RNA, transfer enzymes and guanosine triphosphate (GTP). During protein synthesis, ribosomes move along the message and become detached on completion of the peptide chain[1-4]. Release of the completed peptide chain appears to be rather complex in that (1) the peptide chain is always attached to a molecule of *s*RNA in all stages of

its growth and thus requires some special chemical or enzymatic process to release it from its *s*RNA carrier[5,6], and (ii) peptide chains are not normally released at intermediate stages of growth[4].

It appears reasonable to assume that there is a specific *s*RNA concerned with release of completed polypeptides. In this regard, Brenner[7] and his colleagues have recently provided evidence that this is the case, in their work on nonsense triplets for chain termination. If we then assume that there is a specific *s*RNA concerned with peptide chain release, we can imagine that it must carry an amino-acid of some particular type. Primary and secondary amino-acids cannot function here, as they would form stable peptide bonds with release of a polypeptide containing an additional amino-acid. However, if the releasing *s*RNA carries an amino-acid bearing a tertiary amino function, reaction can still occur, giving a quaternary linkage as shown in equations (1) and (2).

A quaternary bond of the type shown would be very unstable under aqueous conditions and would presumably be readily hydrolysed to the free peptide and tertiary aminoacyl-*s*RNA (2). It seems reasonable to suggest that a similar type of mechanism might be operating in protein synthesis.

Puromycin releases peptide chains from ribosomes at all stages of their growth by competing with and substituting for incoming aminoacyl–*s*RNA[8–11]. In this type of release, the primary amino group of puromycin forms a peptide bond with the growing peptide chain. If the aforementioned suggestion concerning peptide chain release by way of a tertiary aminoacyl–*s*RNA is feasible, it should be possible to demonstrate the release of peptide chains from ribosomes with a derivative of puromycin having its primary amino group changed to a tertiary amino function by introduction of two methyl groups. To test the above hypothesis, therefore, the *N*,*N*-dimethyl-*p*-methoxy-L-phenylalanyl analogue of puromycin (Fig. 3, I) was synthesized and its effect on protein synthesis and peptide chain release investigated.

In Table 1 are shown the results of the *N*,*N*-dimethyl-*p*-methoxy-L-phenylalanyl analogue (hereafter called *N*,*N*-dimethylpuromycin) and puromycin on protein synthesis in a system consisting of rat-liver polysomes and *p*H 5 enzyme. It is seen that the new derivative has approximately 58 per cent of the activity of puromycin (both at 5×10^{-4} M), and definitely inhibits protein synthesis. Further experiments were carried out with polysomes containing [^{14}C]-labelled peptide chains. Fig. 1 shows the effect of *N*,*N*-dimethylpuromycin on the release of peptide chains from pre-labelled polysomes. It can be seen that it has approximately 60 per cent of the activity of puromycin in releasing peptide chains at a concentration of 10^{-3} M. Further, it will be noted that increasing the concentration of the substituted puromycin above 10^{-3} M brings about no increase in its activity. *N*,*N*-Dimethylpuromycin has no effect on the integrity of polysome structure as evidenced by sucrose gradient centrifugation (Fig. 2), in conformity with the results obtained previously with puromycin[12].

The above results demonstrate that 6-dimethylamino-9-(3′-*N*,*N*-dimethyl-*p*-methoxy-L-phenylalanylamino-3′-deoxy-β-D-ribofuranosyl)-purine, a puromycin derivative bearing a dimethylamino-acid (tertiary), is capable of

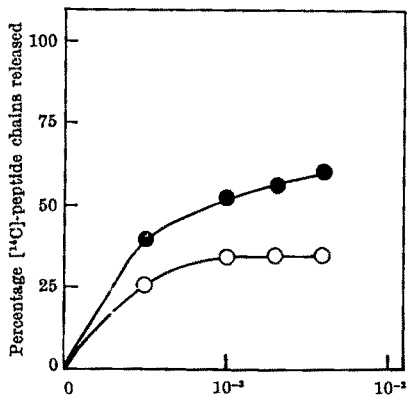

Fig. 1 Release of peptide chains from pre-labelled polysomes by the *N*,*N*-dimethyl-*p*-methoxy-L-phenylalanyl analogue of puromycin and puromycin. Polysomes were labelled in the incubation medium given in Table 1. Incubation was carried out for 10 min at 37° C. The labelled polysomes were diluted with medium *A* (0·25 M sucrose, 0·05 M *tris*-HCl (*p*H 7·6), 0·005 M magnesium chloride and 0·025 M potassium chloride) and isolated by centrifugation at 105,000*g* for 1 h. The resulting pellet was resuspended in medium *A*, and the suspension layered over 0·5 M sucrose (containing medium *A* buffer) and centrifuged at 99,000*g* for 2 h in the No. 30 rotor. The resulting pellet was taken up in medium *A*, and cleared of denatured material by low-speed centrifugation. Treatment with puromycin derivatives: aliquots of the [^{14}C]-labelled polysomes were treated with *N*,*N*-dimethylpuromycin and puromycin for 15 min at 37° C, cooled in ice, diluted with medium *A*, and then isolated by centrifugation at 105,000*g* for 1 h. They were resuspended in 0·02 M *tris*-HCl (*p*H 7·6), 0·004 M magnesium chloride, 0·05 M potassium chloride buffer (TKM buffer) and washed once again by centrifugation as described above. The pellets were finally suspended in TKM buffer and processed for [^{14}C] radioactivity by the 'Millipore' washing procedure of Nirenberg and Leder (ref. 14). Counting was carried out in the Packard scintillation spectrometer. Control polysomes gave 8,458 c.p.m./mμmole ribosome

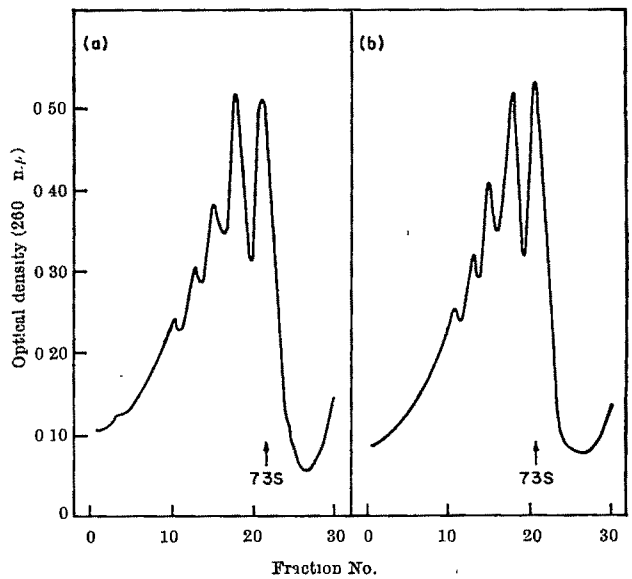

Fig. 2. Sucrose gradient analysis of polysomes pretreated with the *N*,*N*-dimethyl-*p*-methoxy-L-phenylalanyl analogue of puromycin. Polysomes (0·38 mμmoles ribonucleoprotein) in 1·0 ml. of medium *A* were incubated for 10 min at 37° C with and without *N*,*N*-dimethyl puromycin. They were cooled in ice, and then layered on to pre-cooled sucrose gradients (16–34 per cent w/v sucrose containing 0·05 M *tris*-HCl, *p*H 7·6 and 0·005 M magnesium chloride). Centrifugation was carried out in the '*SW* 25·1' swinging bucket rotor at 24,000 r.p.m. for 2·5 h. *a*, Profile of control polysomes; *b*, profile of polysomes pretreated with *N*,*N*-dimethylpuromycin (final concentration 10^{-3} M)

releasing peptide chains from polysomes in the absence of GTP and transfer enzyme. The possible chemical reactions depicting the release of peptide chains by *N,N*-dimethylpuromycin are shown in Fig. 3. We suggest that a similar type of reaction may possibly occur in normal protein synthesis with the releasing *s*RNA carrying a tertiary amino-acid.

Table 1. EFFECT OF THE *N,N*-DIMETHYL-*p*-METHOXY-L-PHENYLALANYL ANALOGUE OF PUROMYCIN AND PUROMYCIN ON PROTEIN SYNTHESIS BY RAT-LIVER POLYSOMES

Each reaction tube contained the following in a final volume of 1·1 ml.: 0·03 M *tris*-HCl (*p*H 7·6), 0·016 M potassium chloride, 0·006 M magnesium chloride, 0·14 M sucrose, ATP (3 μmoles), GTP (1·25 μmoles), phosphoenol pyruvate (12·5 μmoles, potassium salt), pyruvate kinase (60 μg), GSH (5 μmoles, *p*H 7·6), [^{14}C] yeast hydrolysate (1 μc.) (specific activity 1,200 μc./mg), polysomes (0·76 mg ribonucleoprotein), and *p*H 5 enzyme (2·6 mg protein) *N,N*-Dimethyl-*p*-methoxy-L-phenylalanyl-puromycin and puromycin were both dissolved in water and used as such. Incubations were carried out for 10 min at 37° C. Reactions were stopped by the addition of 1 ml. of 10 w/v trichloroacetic acid and the resulting precipitates washed by the procedure of Mans and Novelli (ref. 13). Labelled proteins were finally washed on to 'Millipore' filters with 5 per cent trichloroacetic acid. The filters were dried and counted for radioactivity in the Packard 'Tri-Carb' liquid scintillation spectrometer

Reaction conditions	[^{14}C]-labelled protein c.p.m /mg protein	Percentage inhibition
Control	10,860	—
Puromycin (5×10^{-4} M)	5,163	53
N,N-Dimethylpuromycin (5×10^{-4} M)	7,500	31
N,N-Dimethylpuromycin (10^{-3} M)	7,276	33

6-Dimethylamino-9-(3′-*N,N*-dimethyl-*p*-methoxy-L-phenylalanylamino-3′-deoxy-β-D-ribofuranosyl)-purine was prepared from puromycin dihydrochloride by reductive methylation (formaldehyde, hydrogen, palladium/carbon catalyst). The new compound was characterized by analysis and mass spectrometry. Details concerning its synthesis and mass spectra will be published shortly in conjunction with Dr S. H Eggers of these laboratories.

Nature of the Non-haem Iron in Ferredoxin and Rubredoxin

RECENTLY, Gillard, McKenzie, Mason, Mayhew, Peel and Stangroom[1] presented optical rotatory dispersion data on non-haem iron proteins from several sources. They found that whereas the bacterial ferredoxins from *Clostridium acidi-urici*, *C. pasteurianum* and *Peptostreptococcus elsdenii* and the rubredoxin from *P. elsdenii* have very similar optical rotatory dispersion spectra in both the oxidized and reduced forms, these spectra differ qualitatively from that obtained with oxidized plant (parsley and spinach) ferredoxin. No data were presented on reduced plant ferredoxin, and indeed it has been reported[2] that reduced plant ferredoxin has no optical activity in the visible region of the spectrum. Gillard *et al.* consequently suggested 'that the bonding of iron in plant ferredoxin is entirely different from that in bacterial ferredoxin and rubredoxin".

Recently, we obtained measurements of both optical rotatory dispersion and circular dichroism on plant ferredoxin[3] and confirmed the earlier data which Gillard *et al.* and earlier workers[2,4] had reported, with the exception that we were unable to find the trough at 330 mμ (see ref. 1, Fig. 3). Furthermore, we extended these measurements to reduced ferredoxin; in contrast to the earlier report[2], we found intense and detailed optical activity in the chemically reduced species in the visible region of the spectrum. However, this disappears slowly with a concomitant irreversible denaturation of the protein. The circular dichroism spectra indicate the presence of at least eight optically active transitions between 300 and 700 mμ in the oxidized and reduced proteins.

More pertinent, however, are some recent electron paramagnetic resonance (EPR) results which were not available to Gillard *et al.* Briefly, these can be summarized as follows. (i) Spinach ferredoxin exhibits no electron paramagnetic resonance spectrum in its oxidized form. On reduction, a spectrum typical of the $g = 1{\cdot}94$ class of iron proteins is obtained[5]. (ii) *C. pasteurianum* ferredoxin gives a variable amount of a $g = 2{\cdot}0$ signal in the oxidized form and develops strong resonance in the $g = 1{\cdot}94$ region on reduction[6]. However, whereas the line-shape of spinach ferredoxin is readily understood, that of the bacterial ferredoxin is not. (iii) *C. pasteurianum* rubredoxin exhibits a strong $g = 4{\cdot}3$ signal in the oxidized form and nothing on reduction[7,8]. Table 1 contains a summary of this and other pertinent data.

The prediction made by Gillard *et al.* on the basis of their optical rotatory dispersion results, that the binding of iron in rubredoxin should be quite similar to that of

Table 1

	Visible optical absorption		Visible optical activity		EPR* signals		Labile sulphide	Redox potential	Ref.
	Oxidized	Reduced	Oxidized	Reduced	Oxidized	Reduced			
Spinach ferredoxin	Strong	Strong	Strong	Strong	None	$g = 1.94$	Yes	−0·432	3, 5, 9
C. pasteurianum ferredoxin	Strong	Strong	Strong	Weak	$g = 2.0$ (variable)	"$g = 1.94$"	Yes	−0·42	1, 6, 10
C. pasteurianum rubredoxin	Strong	None	Strong	Weak	$g = 4.3$	None	No	−0·06	1, 7, 8, 11

* Electron paramagnetic resonance.

the bacterial ferredoxins, is not substantiated by our electron paramagnetic resonance data. The electron paramagnetic resonance spectrum of rubredoxin is of the high-spin type found with ferrichrome and transferrin[13]. However, the ferredoxins have spectra which would seem to be due to low-spin iron in tetrahedral symmetry. Furthermore, the contents of Table 1 indicate that the only satisfactory way to classify these three proteins is individually. However, as has been well known[15], the plant and bacterial ferredoxins have much more in common with each other than either has with rubredoxin; even so, the observed differences are real and cannot be rationalized at this time.

Attempts to determine the ligand environment of these proteins should not be based on the application of one experimental method alone. In particular the results of Mössbauer, magnetic resonance, optical and circular dichroism spectroscopy should all be considered in our attempts to define the molecular orbital configurations of this important new class of electron-transfer proteins.

Chromogen Formation and Degradation of *N*-Acetylhexosamines and *N*-Acetylneuraminic Acid by Barium Hydroxide Treatment

ALKALINE degradation[1] has been used as a means of determining the structures of oligo- and poly-saccharides. Various alkalis have been used as degradation reagents. The barium hydroxide technique especially has been effectively used for the exploration of the chemical structure of the carbohydrate moieties of some sialomucoproteins[2–4]. Under the conditions of the barium hydroxide treatment, *N*-acetylglucosamine[5] and *N*-acetylneuraminic acid[2] are partly converted into chromogen I (ref. 5) and *N*-acetylhexosamine, respectively. However, none of the reactions of *N*-acetylhexosamines and *N*-acetylneuraminic acid with barium hydroxide has as yet been completely examined. The present work was undertaken to obtain more detailed knowledge of the chromogen formation and degradation of the *N*-acetylhexosamines and *N*-acetylneuraminic acid under the conditions of barium hydroxide treatment.

A solution of 20 mg of a sample in 4 ml. of 0·02 N barium hydroxide solution was heated at 80° C for 15 min and cooled. The cooled mixture was neutralized to *p*H 5·5 with 0·1 N sulphuric acid and centrifuged. The precipitate was washed with water and the washings and supernatant solution were combined. Half the combined solution was evaporated over phosphorus pentoxide in a vacuum desiccator. 0·3 ml. of water was added to the dry residue and the mixture centrifuged. The supernatant solution was subjected to the two-dimensional paper electrophoresis and chromatography as described in a previous article[6]. 0·5 ml. of 2 N sulphuric acid and 0·25 ml. of 2,4-dinitrophenylhydrazine reagent[7] was added to the other half of the combined solutions. The mixture was allowed to react overnight at 37° C and diluted to 20 ml. with water and then shaken with three successive portions of ethyl acetate—10, 5 and 5 ml. respectively. The combined solvents were washed with water and extracted with three 10-ml. portions of 3 per cent sodium bicarbonate. The solvent was washed with water and evaporated. The dry residue was designated as the neutral carbonyl compound fraction. The combined sodium bicarbonate extracts were acidified with 4 N sulphuric acid and re-extracted with three 10-ml. portions of ethyl acetate, and the solvents were washed with water and evaporated. The dry residue was designated as the keto acid fraction. The two fractions were subjected to ascending paper chromatography. (The solvent used for 2,4-dinitrophenylhydrazones of aliphatic carbonyl compound was methanol-hexane (1 : 1) (ref. 8). The solvents for keto acid 2,4-dinitrophenylhydrazones were *n*-butanol saturated with 3 per cent aqueous ammonia[9,10] and *n*-butanol-ethanol-water (5 : 1 : 4) (ref. 10).)

The results of the barium hydroxide treatment of *N*-acetylglucosamine, *N*-acetylmannosamine and *N*-acetylgalactosamine followed by two-dimensional separation of the reaction products are summarized in Table 1. Spots 1, 3, 4, 9 and 10, produced from the three *N*-acetylhexosamines, were classed as chromogens on the basis of their reactivities in colour tests 1 (the indirect Ehrlich reaction)[6] and 2 (the direct Ehrlich reaction)[6]. The chromogens appear to be furan derivatives, since these violet or pink colours fade within 1–2 h. Of these furan chromogens, spot 3 was the main chromogen at all times and identified as chromogen I (ref. 5) by its electrophoretic and chromatographic mobilities (Table 2). Spots 2, 5 and 7 were identified as *N*-acetylglucosamine, *N*-acetylgalactosamine and *N*-acetylmannosamine, respectively, on the basis of their reactivities in colour tests 1 and 2 and their mobilities. Spots 6 and 8 were unknown 2-acetamido-2-deoxy-aldoses. The results show that under the conditions of barium hydroxide treatment, the main reaction products of the three *N*-acetylhexosamines are furan chromogens which include chromogen I. Each *N*-acetylhexosamine gave an unidentified 2-acetamido-2-deoxy-aldose as a by-product and reversible epimerizations of *N*-acetylglucosamine and *N*-acetylmannosamine occur simultaneously as side reactions.

After *N*-acetylneuraminic acid was treated with barium hydroxide, the reaction products obtained were subjected to two-dimensional paper electrophoresis and chromatography. The results are shown in Table 3. Since spots 6–9 from *N*-acetylneuraminic acid gave pink violet colours which were stable for several days, these spots are likely to be *N*-acetylneuraminic acid and its derivatives, or pyrrole compounds derived from the acid by the barium hydroxide treatment. Of these spots, numbers 7 and 9 were identified as *N*-acetylneuraminic acid and pyrrole-2-carboxylic acid[11], respectively, by their electrophoretic and chromatographic mobilities. Spots 2, 5

and 3, produced from *N*-acetylneuraminic acid, were identified as *N*-acetylglucosamine, *N*-acetylmannosamine and chromogen I, respectively, by their mobility and by their reactivities in colour tests 1 and 2. Paper chromatography of the neutral carbonyl compound and keto acid fractions obtained from the *N*-acetylneuraminic acid by the barium hydroxide treatment showed that *N*-acetylneuraminic acid produced pyruvic acid and acetaldehyde. These results indicate that under the conditions of the barium hydroxide treatment, *N*-acetylneuraminic acid is degraded into two groups, one of which consists of *N*-acetylmannosamine, *N*-acetylglucosamine, an unidentified 2-acetamido-2-deoxy-aldose, furan chromogens, including chromogen I, pyruvic acid and acetaldehyde, and the other is pyrrole chromogens, including pyrrole-2-carboxylic acid. Since it is clear[12] that the *N*-acetylhexosamine fragment present in the *N*-acetylneuraminic acid molecule is *N*-acetylmannosamine, *N*-acetylglucosamine formed in the degradation of the *N*-acetylneuraminic acid by the barium hydroxide treatment seems to be an epimerization product of the *N*-acetylmannosamine which derived from the acid by the treatment.

These findings indicate that in general the chromogen formation and epimerization of the *N*-acetylhexosamines in barium hydroxide solution are similar to those of the *N*-acetylhexosamines in sodium hydroxide[13], carbonate[5] and pyridine–nickelous acetate[13] solutions. Furthermore, the degradation of *N*-acetylneuraminic acid in barium hydroxide solution to *N*-acetylmannosamine, *N*-acetylglucosamine and pyruvic acid is similar to that of *N*-acetylneuraminic acid in sodium hydroxide[15] and pyridine–nickelous acetate[13] solutions. The reactions of the three *N*-acetylhexosamines and *N*-acetylneuraminic acid with barium hydroxide can be depicted as in Fig. 1.

Bone Marrow Sulphydryl Levels

DURING the course of other investigations the sulphydryl levels of rat bone marrow have been measured. Unlike other tissues examined, the bone marrow was found to show a high protein-bound sulphydryl level and a relatively low acid-soluble sulphydryl level. The investigation was extended to determine whether this unusual distribution of sulphydryl was a feature of other bone marrows.

All animal bone marrows were forced out of the femora of freshly killed animals by air pressure. The human specimens were obtained by sternal puncture. Estimations of total sulphydryl were made by the method of Calcutt and Doxey[1] using *p*-chloro-mercuribenzoic acid as the reactant. Acid-soluble sulphydryl was determined by the variation of the above method devised by Calcutt, Doxey and Coates[2], using trichloroacetic acid as the protein precipitant. The difference between the total sulphydryl and the acid-soluble sulphydryl levels as determined on two samples of the same marrow was taken as representing the protein-bound sulphydryl value.

The results for the animal experiments are shown in Table 1. It was noted that the rabbit marrow was extremely fatty in comparison with the others, and this may partly explain the lower total and protein-bound values obtained. It was also found that, proportionate to their size and weight, rats of the Wistar strain have considerably larger amounts of femoral marrow than do rats of the August strain.

Findings in respect of the human cases are given in Table 2. These samples were all taken from hospital patients (diagnoses are shown in the Table), and the possibility of the results being affected by the illness cannot be excluded. Nevertheless, the same general feature of high protein-bound sulphydryl and low acid-soluble sulphydryl is apparent.

The values for acid-soluble sulphydryl found in this work were lower than those previously obtained from animal livers but rather higher than those found for muscle, kidney, spleen or a range of animal tumours[3]. The present values are, however, considerably lower than those previously recorded by Lutwak-Mann for rat marrow (150–198 mg/100 g)[4]. This may arise from the fact that these last values were obtained by the non-specific iodometric method. An earlier investigation[5] gave 0·5 mg/100 g of glutathione for rabbit marrow. This is much lower than the present figures but, as no details of method were given, comment is not possible.

The protein-bound sulphydryl levels found in the present work are much higher than any previously found for other tissues. Liver has shown the highest values for normal tissues with levels up to about 7·5 μg sulphydryl per 100 mg wet weight[6], while one tumour has given 10·65 μg sulphydryl/100 mg wet weight[7]. This raises the question as to why bone marrow should have such unusually high levels of protein-bound sulphydryl. Possible explanations are: (1) marrow cells have protein with more than the normal number of cysteine residues; (2) the marrow cell protein has a greater than usual exposure of sulphydryl groups; or (3) the marrow cells contain much more protein than do other cells. Some further evidence is available in measurements of the total sulphydryl levels in denatured specimens of August bone marrow. A 1 per cent solution of 'Teepol' (Shell Chemical Co., Ltd.) was used to denature the homogenized marrow, this method having previously[6] been found to be a very effective one. Using marrow from six male rats, a mean value of 35·8 μg sulphydryl per 100 mg wet weight of tissue and a range of 24·8–50·9 were obtained. This value is only a little above the total sulphydryl values for male August rats and suggests that in bone marrow most of the protein-bound sulphydryl is normally exposed. This contrasts with previously[6] obtained values for liver and tumours where only one-twelfth to one-thirtieth of the protein-bound sulphydryl was normally found exposed.

These findings have a particular interest in respect of the great sensitivity of bone marrow to certain cytotoxic agents. It has already been suggested by Calcutt and Connors[7] that sensitivity to alkylating agents is correlated with a high ratio of protein-bound to acid-soluble sulphydryl. It now appears that bone marrow has such a high ratio and in fact one which is higher than for any other tissue so far examined. At the same time bone marrow sensitivity to alkylating agents is a limiting factor in their use.

Table 1. LEVELS OF SULPHYDRYL IN ANIMAL BONE MARROWS

Species	Sex	No. of samples	Total sulphydryl	Acid-soluble sulphydryl	Protein-bound sulphydryl
Rat (August)	M	10	29·9 (23·2–36·0)	5·9 (4·1–9·9)	24·0 (16·7–30·1)
Rat (August)	F	10	33·5 (29·3–39·0)	5·8 (2·3–8·4)	27·6 (21·6–33·6)
Rat (Wistar)	M	6	45·7 (40·6–52·3)	9·5 (6·0–13·1)	35·0 (28·6–44·5)
Rat (Wistar)	F	6	44·8 (31·1–53·7)	10·8 (7·7–14·0)	34·0 (19·7–41·3)
Guinea-pig	M	6	35·6 (28·9–46·1)	10·2 (7·6–12·3)	26·9 (18·5–35·4)
Rabbit	M	5	14·9 (12·3–16·2)	6·8 (3·5–9·5)	8·1 (6·1–9·8)

For each value the mean and range (in parentheses) are shown. All values are expressed as μg sulphydryl/100 mg wet weight of tissue.

Table 2. LEVELS OF SULPHYDRYL IN HUMAN BONE MARROW

Sex	Age	Diagnosis	Total sulphydryl	Acid-soluble sulphydryl	Protein-bound sulphydryl
M	57	Carcinoma of stomach	12·3	1·6	10·7
M	68	Lymphosarcoma	10·2	1·8	8·4
M	39	Melanoma	17·1	1·9	16·2
M	78	Mycosis fungoides	23·7	3·5	20·2
F	62	Plasmacytoma	15·9	1·3	14·6
F	47	Thyroid enlargement	18·6	3·1	15·5
F	20	Disseminated lupus erythematosus	9·2	2·1	7·1
F	78	Carcinoma of colon	9·4	1·1	8·3

I thank Dr. Anne Bromley of the Department of Pathology, Mount Vernon Hospital, for supplying the human bone marrow specimens. The expenses of this work were defrayed from a block grant by the British Empire Cancer Campaign for Research.

Normal Human Serum Fluoride Concentrations

RESULTS from a new method of analysis of fluoride from serum indicate that the generally accepted value for normal humans is too high by as much as a factor of ten. The average serum fluoride concentration of sixteen non-fasting individuals, all presumably drinking fluoridated water, was found to be 0·7 μM ± 0·4 *S.D.* (0·013 p.p.m.) and the average difference in duplicates was 0·18 μM. (The very low values found here for serum fluoride make p.p.m. an awkward unit. Therefore the shift has been made to the more useful and acceptable chemical concentration terms, mμmole (millimicromole) and μM (micromolar).) The generally accepted average serum fluoride value is 8 μM (0·15 p.p.m.) as found by Singer and Armstrong, regardless of the concentration of fluoride in the drinking water up to 130 μM (2·5 p.p.m.)[1].

The method is being published in detail elsewhere, but essential features are diffusion at 25° C from 3 N hydro.

chloric acid and an indicator which depends on the loss of fluorescence of a morin thorium complex. As little as 1 mμ mole of fluoride (0·02 μg) in a volume of 3 c.c. is able to reduce the fluorescence 50 per cent. Diffusion of the hydrogen fluoride into 0·1 N sodium bicarbonate is enhanced by means of a rotary shaker. The diffusion dishes are non-wettable polystyrene ('Falcon') with the septum in the outside compartment partially removed and the lids sealed with a silicone grease.

The crucial difference in this procedure as compared with that of Singer and Armstrong lies in the conditions for the diffusion process. Sera from six adults, run under conditions similar to those of Singer and Armstrong[2] (diffusion from 3 N perchloric acid to 2·5 N sodium hydroxide at 60° C), were found to have apparent fluoride values within the range that they find, 6–10 μM. One of these samples was then tested for heat stability using fluorine-18 as a control. After diffusion the sodium hydroxide solution was converted to a mixed carbonate–chloride salt which was fused in platinum crucibles over a burner. Blanks and standards were similarly treated and all were labelled with fluorine-18. Results showed only about a 10 per cent loss of fluorine-18, but there was a 90 per cent loss of apparent fluoride. Quadruplicate values for the non-fused serum samples ranged from 9 to 11 μM while the fused samples ranged from 0·9 to 1·7 μM (figures corrected for the loss during fusion). Standards treated the same way showed a 10 per cent loss of both fluorine-18 and fluorine-19. Serum samples diffused by the new method and then fused showed a 10 per cent loss of fluorine-18 and little or no loss in measured fluorine-19.

There has been other evidence, largely ignored, that the serum fluoride values reported by Singer and Armstrong are too high. Their results are most easily explained by a hypothesis that their serum fluoride values are too high by some large relatively constant error. The average serum fluoride values they report are the same whether the individuals are drinking 5 μM (0·1 p.p.m.) or 130 μM (2·5 p.p.m.) fluoride in the water[1]. This seems unreasonable, because with this difference of fluoride intake the incidence of dental mottling increases from 0 to 90 per cent[3] and the average bone[4] and the urine[5] fluoride concentrations change several-fold.

Data from their study on the clearance of radioactive fluoride, if applied to the serum fluoride values determined at the same time[6], indicate that the urine fluoride concentrations went as high as 800 μM (15 p.p.m.). Based on the amount of ingested fluoride and water this figure would have been expected to be less than 150 μM (3 p.p.m.) (ref. 7). The most likely explanation again seems to be that the serum value is in error by a factor of at least five.

Hall, using a new colorimetric method, which appears to be sensitive enough to detect serum fluoride-levels of about the magnitude that Singer and Armstrong claim, states that he rarely finds detectable amounts[8].

Smith, Gardner and Hodge in 1950 found average non-fasting blood fluoride-levels of 1·8 μM ± 1·2 *S.D.* (0·04 p.p.m.) in a community on fluoridated water[9]. Their method was cumbersome and they had to apply a correction factor due to losses occurring during the double distillation and ashing of the 50 c.c. of serum[10], but the work should receive more consideration than it has, because it is the only study to show a difference in serum fluoride concentrations of those living on fluoridated water (1·8 μM) as compared with those on non-fluoridated water (0·7 μM, '*P*' value of the difference given as 0·010). The range of values they found was 0–4 μM (0·072 p.p.m.). The difference between their average value and that reported here probably is due to analytical problems but may be due to sampling. The most likely reasons for sampling problems are a difference in the ages of the subjects and inclusion of subjects with sub-clinical kidney or bone disease. The group here averaged 24 years of age with a range of 17–40; their group averaged 42 years of age with a range of 27–53 (ref. 9).

I thank Dr. William George for supplying the blood samples from persons undergoing pre-employment physical examinations, and Mrs. Joy Howe for technical assistance.

Effect of Arabolic Androgens on Tissue Replacement in the Ear of the Rabbit

IT was recently reported that, when tissue of 1 cm² area was excised through the full thickness of the pinna of the rabbit's ear, regeneration occurred. Furthermore, the rate of regeneration was significantly greater in males than in females[1,2]. It was suggested that the rate of regeneration might be influenced by male sex hormones. If this were so, then treatment of females with androgens should increase the rate of regeneration. Two androgens were used in experiments to test this hypothesis: (*a*) androst-4-en-17β-3-one-phenyl-propionate (testosterone phenylpropionate—TPP)—a steroid with highly androgenic and some anabolic activities, closely allied to the naturally occurring steroid testosterone; (*b*) 19-*nor*-androst-4-en-17β-3-one-phenyl-propionate (nandrolone phenylpropionate, NPP, or 'Durabolin')—a steroid with less androgenic but more anabolic activity than testosterone phenylpropionate, and therefore more suitable for the treatment of females.

Tissue of 1 cm² was removed from the ears of adult male and female rabbits under 'Nembutal' anaesthesia. Four groups of animals were given subcutaneous injections as follows: (1) six females, 25 mg TPP/3 kg body-weight, twice weekly; (2) six females, 1 mg TPP/3 kg body-weight, five times weekly; (3) six females, 17·5 mg NPP/3 kg body-weight, twice weekly; (4) six females, 1 mg NPP/3 kg body-weight, five times weekly. Group 5 (twelve females) and group 6 (eighteen males) were left untreated. The steroids injected were dissolved in sesame oil, to which 0·5 per cent phenol had been added as a bacteriostatic.

Photographs, taken every 7 days, recorded the progress of regeneration. The area of the new tissue and the degree of contraction were determined from transparencies by the 'square-counting' method described in a previous communication[1]. Growth measurements were commenced at 14 days, after shedding of the scab had revealed the junction between old and new tissue.

The rates of growth in area of the regenerates after treatment with TPP are shown in Fig. 1. In this, and in Fig. 2, each point on the graph represents the arithmetic mean of measurements at a particular time for all the members of a group, and the mean growth recorded was arrived at after correction for contraction. By means of analyses of variance it can be shown that treatment of female animals with TPP (groups 1 and 2) increases the growth of ear tissue significantly ($P < 0·005$ in both cases) in comparison with the amount of growth in un-

treated females (group 5). After 21 days there is a close similarity between the growth curves for untreated males (group 6) and for females treated with TPP at a high dose-level (group 1). This similarity may be coincidental, but it seems to indicate that the higher rate of tissue regeneration normally found in males is, in fact, due to their androgen-level.

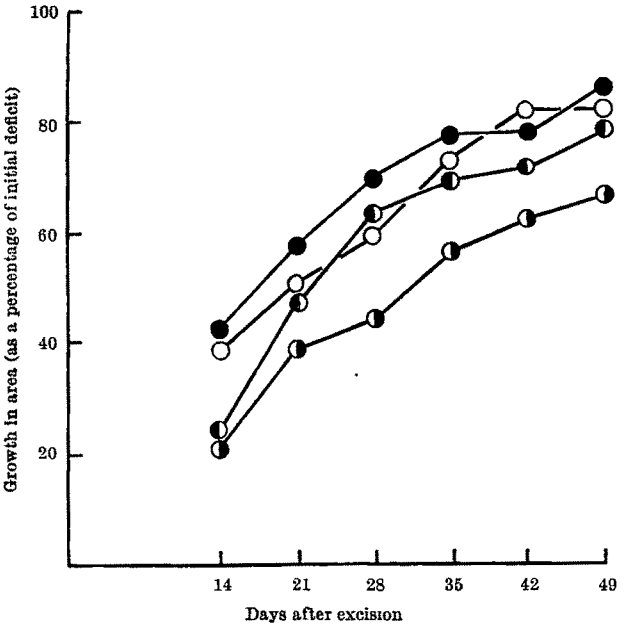

Fig. 1. Comparison of the rates of growth of the ear regenerates of TPP-treated animals and those of untreated animals. ●, High TPP female; ○, low TPP female; ◐, untreated male; ◑, untreated female

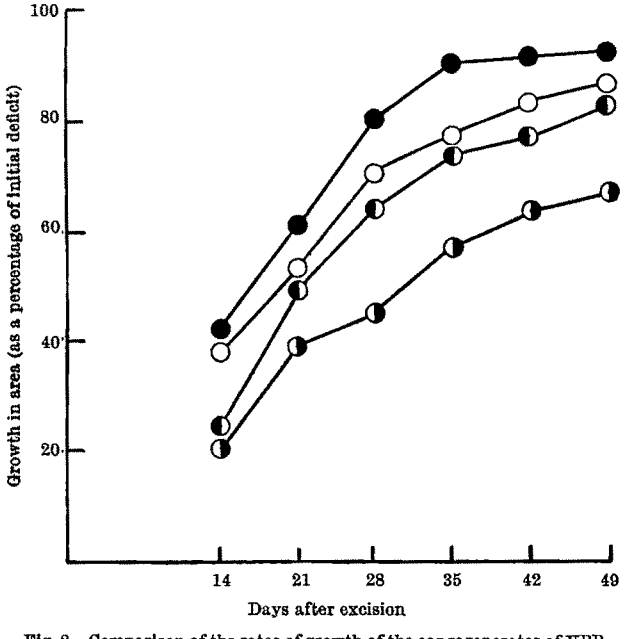

Fig 2. Comparison of the rates of growth of the ear regenerates of NPP-treated animals and those of untreated animals. ●, High NPP female; ○, low NPP female; ◐, untreated male; ◑, untreated female

The rates of growth of the regenerates after treatment with NPP are shown in Fig. 2. Analyses of variance show that treatment of female animals with NPP (groups 3 and 4) increases the growth of ear tissue significantly ($P < 0.005$ in both cases) in comparison with growth in untreated females (group 5). The effect of a low dose-level of NPP on the rate and extent of growth of the tissue regenerate of females closely resembles the effect of a high dose-level of TPP. The effect of NPP at a high dose-level was shown by analyses of variance to be significantly greater than the effect of TPP at either high or low dose-levels ($P < 0.005$ in both cases), and this, together with its lower androgenicity, makes it a more suitable growth-stimulating agent. The growth curves of untreated males, for females treated with low doses of NPP, and for females treated with high doses of TPP, are all very similar. Treatment with either steroid causes a steepening of the gradient of the linear portion of the growth curve (indicating a rate increase) and the point of inflexion occurs earlier than in untreated animals.

The following conclusions can be drawn from these experiments: (1) Androgens stimulate the rate of tissue regeneration in females. (2) It can be assumed that the higher rate of growth in males as compared with females is due to the higher androgen-level in the former. (3) Nandrolone phenyl propionate is more effective than testosterone phenyl propionate in increasing the rate of regeneration in females.

As a further test of validity of this hypothesis, the effect of lowering the androgen-level on the reparative rate in males is being investigated.

We thank the Endowments Committee of Guy's Hospital for a grant towards the expenses of this investigation, Dr. W. R. Buckett and Dr. W. J. Tindall, of Organon Laboratories, Ltd., for their helpful advice and the supply of steroids used in this investigation, and Mr. E. Quinn for his technical assistance.

Protective Effect of Some Neutral Solutes on the Inactivation of Myosin A-Adenosinetriphosphatase

MYOSIN-ATPASE is a labile enzyme the activity of which is easily destroyed by various physical or chemical operations during preparation such as heating[1-6], freezing and thawing[7], lyophilizing[8], and shifting the *p*H of the solution to the acid or alkaline side[6,9,10]. Hence, the only means of storage of this enzyme after preparation has been to keep it a little above 0° C and at a neutral *p*H. Under these conditions, it retains its activity for a few weeks.

Recent developments in methods of deep-freezing and lyophilization have made possible the storage of various biological materials while maintaining structural and functional integrity. It has been found empirically that several labile substances from living cells or tissues maintain their original biological functions through processes of freezing and thawing or lyophilization by the addition of certain inert organic compounds[7,11-14]. Though no explicit study has yet been undertaken, myosin also has been shown to behave in a similar way[8]. This communication reports investigations on the protective effect of some organic compounds containing hydroxyl group(s) (sugars and alcohols) on the inactivation of myosin A-ATPase caused by warming, freezing and thawing, lyophilization, and [H^+].

In Table 1 are illustrated the changes in the activity of myosin A before and after incubation at 35° C and *p*H 7·0 for 30–60 min in the presence of some sugars and alcohols. All compounds tested, except methyl alcohol and ethylene glycol, showed a protective effect against thermal inactivation of the enzyme. Although considerable inactivation

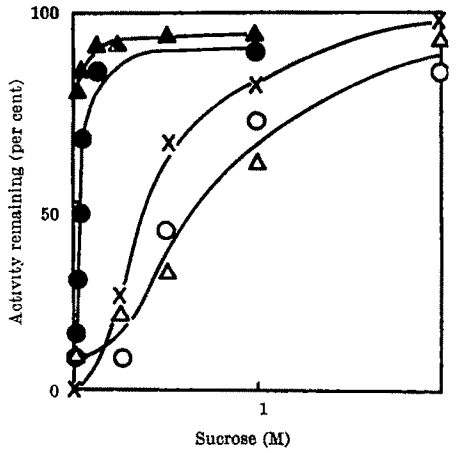

Fig. 1. Protective effect of sucrose on the inactivation of myosin A–ATPase activity. Freezing and thawing (▲), myosin A (2·0 mg/ml.) in 0·5 M potassium chloride, 50 mM *tris*-maleate buffer at *p*H 6·0 and 0–1·0 M sucrose was stored in a deep-freezer at −15° C for a week and thawed in a bath at 20° C within 5 min. Lyophilization (●), myosin A(~10 mg/ml.) in 0·5 M potassium chloride, 20 mM *tris*-maleate buffer at *p*H 6·0, and 0–1·0 M sucrose was lyophilized and stored at −15° C. When used, the samples were dissolved by distilled water in a volume equal to the original and equilibrated overnight at 3° C. Incubation at 35° C and *p*H 7·0 for 90 min. (△), Incubation mixture contained 2 mg/ml. myosin A 0·5 M potassium chloride, 20 mM *tris*-maleate buffer, and 0–2 M sucrose. Incubation at *p*H 6·0 and 3° C for 18 h. (○), Incubation mixture contained 2·0 mg/ml. myosin A, 50 mM *tris*-maleate buffer, 0·5 M potassium chloride and 0–2 M sucrose. Incubation at *p*H 10 3 and 3° C for 18 h. (×), Incubation system was the same as at *p*H 6 0 except that 50 mM glycine-potassium hydroxide buffer was used in place of *tris*-maleate buffer. All ATPase activity measurements were conducted in the following mixture at 21° C and *p*H 7·0: 0·5 M potassium chloride, 50 mM *tris*-maleate buffer, 5 mM calcium chloride, 1 mM ATP, 0·2 mg/ml. myosin A, and less than 0·2 M sucrose. P_i was determined by the same method as described in Table 1. Myosin A was prepared by the method of Perry (ref. 17)

of the enzyme was observed before incubation at 35° C when the activities were measured in the reaction system with high concentrations of the sugars and alcohols, the apparent inactivation was almost completely reversed, except in the case of methyl alcohol, as the concentrations of these organic compounds in the system were diminished by dilution. The same reversibility also held in the case of sucrose, fructose and glycerol even after incubation for 30 and 60 min at 35° C. Then the reversed activities were very close to those before thermal treatment, while a large percentage of the enzymatic activity of the control was lost by the same treatment.

On the other hand, despite its ability to cause the reversible inactivation of myosin A-ATPase before incubation, ethylene glycol has no influence over the thermal denaturation of the enzyme. The activity destroyed by incubation at 35° C is no longer reversible in this case. Since it has been suggested by Brahms and Kay[15,16] that the unfolding of the protein helical structure is intimately involved in the changes of the ATPase activity of myosin A examined in varying concentrations of ethylene glycol, the action of this alcohol differing from those of glycerol and the sugars to thermal inactivation of myosin A-ATPase may originate from this effect of ethylene glycol on the protein structure.

Fig. 1 summarizes the effects of sucrose on inactivation of myosin A. It protects against inactivation of myosin A by high (10·3) and low (6·0) *p*H, freezing and thawing, lyophilization, and heat. The differences in concentrations of sucrose necessary for protection against inactivation by *p*H and heat and inactivation by lyophilization and freezing and thawing may possibly be due to concentration of the solutions during freezing. The mechanism of the protective effect of these organic compounds on the inactivation of myosin A–ATPase is not yet known. Further investigations are in progress and will be published elsewhere.

Table 1. EFFECTS OF SUGARS AND ALCOHOLS ON MYOSIN A–ATPASE ACTIVITY BEFORE AND AFTER INCUBATION AT 35° C AND *p*H 7 0

Conc. of sugars or alcohols during incubation (M)		Conc. of sugars or alcohols in reaction mixture (M)	ATPase activity (μmoles P_i g^{-1} sec^{-1}) Before incubation	After incubation

Effect of Insulin on Purified Creatine Phosphokinase

THE effects of insulin can be readily demonstrated on a variety of metabolic processes in intact cells both *in vivo* and *in vitro*; however, the exact site of insulin action remains unexplained. Numerous investigators have proposed that the effects of insulin are mediated through its action on one enzyme or one enzyme system, but no such action has been consistently demonstrable. During an investigation involving the effects of insulin on certain aspects of creatine metabolism, I have found that insulin enhances the activity of a purified enzyme, creatine phosphokinase, *in vitro*. The reaction involved is the following:

$$\text{Creatine-PO}_4 + \text{ADP} \xrightarrow[\text{Mg++}]{\text{Insulin}} \text{creatine} + \text{ATP}$$

The physiological significance of this observation requires further enquiry; however, this *in vitro* effect is easily and consistently demonstrated.

The insulin effect was observed under a wide range of conditions. In most experiments 1·0 ml. of the following incubation mixture was used.

Creatine phosphokinase	About 1·0 μg/ml
Tris buffer	0·05 M
Creatine phosphate	0·02 M
Adenosine diphosphate	0·02 M
Magnesium acetate	0·02 M
Cysteine	0·02 M

The creatine phosphokinase was purified rabbit enzyme obtained from C. F. Boehringer und Soehne *G.m.b.H.*, Mannheim, Germany, or from Sigma Chemical Co., St. Louis, Missouri. Insulin was obtained from Eli Lilly and Co., Indianapolis, Indiana, or from E. R. Squibb and Sons, New York. The insulin was diluted to the required concentration with buffer before it was added to the incubation mixture. The entire mixture was prepared with the exception of the adenosine diphosphate (ADP), and the reaction was initiated by addition of the latter. A blank was included for each test and was identical to the incubation mixture except for the substitution of water for ADP. The incubation was carried out at 37° C and *p*H 7·40 for 10 min. After incubation, magnesium was chelated with a 10 per cent excess of ethylenediamine tetraacetic acid (EDTA), a barium hydroxide–zinc sulphate filtrate was made, and creatine was determined by a method previously described[1,2]. Subtraction of the blank value from the test value gave the creatine formed from creatine phosphate by the action of creatine phosphokinase. Fig. 1 illustrates the dose-response curve obtained under the described conditions.

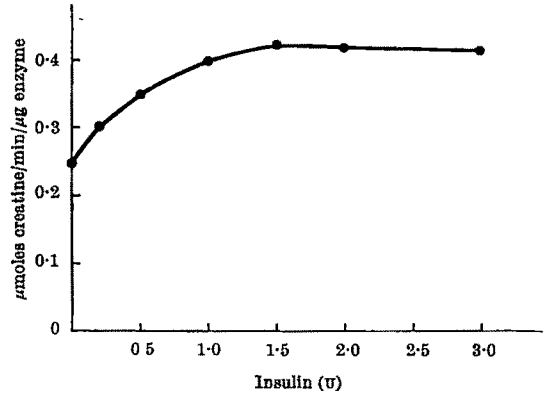

Fig. 1. The effect of varying amounts of insulin on creatine formation by purified creatine phosphokinase

An extensive series of experiments was undertaken in an attempt to rule out artefactitious causes for the observed effect. These experiments provided the following information: (1) Insulin after being heated with 1·0 N sodium hydroxide for 30 min was inactive. (2) Creatine phosphokinase and insulin from two independent sources gave similar results. (3) Zinc at concentrations found in insulin and at higher concentrations either had no effect or inhibited the reaction. (4) Glycerol and phenol, which were the preservatives in the insulin used, were without effect at the concentrations present. (5) Addition of purified bovine albumin instead of insulin had no effect. (6) None of the constituents in the incubation mixture except creatine had any effect on the reaction used for quantitation. Magnesium produced a slight interference but was removed with EDTA before measurements were made of the creatine. (7) No effect of insulin on the reverse reaction (ATP + creatine → ADP + creatine-phosphate) could be demonstrated.

The insulin effect was demonstrated in numerous experiments involving several hundred incubation mixtures. The enhancement of creatine phosphokinase activity usually represented a 60–100 per cent increase in rate of product formation. It is of interest to note that cysteine and other sulphydryl compounds have a similar activating effect on the forward reaction but not the reverse reaction[3]; however, it appears unlikely that the sulphydryl groups *per se* on the insulin chains are responsible for the observed effect as there is a several-thousand-fold excess of sulphydryl groups already present in the incubation mixture. Cysteine is not necessary in the incubation mixture for demonstration of the insulin effect, but its addition results in closer replicates and more linear dose-response curves. Calculation of the molar ratio between insulin and enzyme under the conditions of our experiments indicates that maximum effect was attained with a ratio of about 100 : 1. The conditions of incubation were not selected as the optimum conditions for the lowest insulin-enzyme ratio, however.

The relationship between the action of insulin on creatine phosphokinase and its known effects in the intact animal is now being investigated; however, I would like to suggest that a physiological significance for this action is not unreasonable. Insulin has been shown to affect numerous processes in the animal, including glucose uptake, glycogen synthesis, incorporation of amino-acids into protein and fatty acid synthesis. The diverse effects of insulin in the intact animal indicate that we must consider two possibilities in any attempt to formulate a hypothesis to explain its action. This diversity of effects may be caused by numerous discrete actions on different enzymes, enzyme systems or membranes, but a more attractive possibility is that insulin has only one basic action and that other observed phenomena are secondary to this. The common link between most of the known effects of insulin appears to be a requirement for energy, and it is clear that the net result of the demonstrated effect of insulin on creatine phosphokinase would be to increase the rate at which energy in the form of ATP is made available.

It is of interest that the tissue in which an insulin effect is most easily demonstrated is skeletal muscle, and it is this tissue which has the highest concentration of creatine phosphokinase. Liver, a tissue in which an insulin effect is less easily demonstrated, contains lesser amounts of creatine phosphokinase than does muscle. Since insulin has an effect on isolated adipose tissue, absence of creatine phosphokinase from this tissue would cast doubt on a possible physiological role for the observed action. Since no data on creatine phosphokinase activity in adipose tissue could be found, some preliminary experiments were undertaken to investigate this question. The dorsal fat pads of 250 g female rats were homogenized in a Vertis homogenizer with 40–80 volumes of *tris* buffer. The homogenates were tested in the system described above using homogenate instead of purified enzyme. Adipose tissue was found to possess appreciable creatine phosphokinase activity. Brown adipose tissue had a much higher creatine phosphokinase activity than did white adipose tissue. Thus, on the basis of available information, creatine phosphokinase is present in all tissues in which definite insulin effect can be demonstrated.

Numerous questions are immediately raised by the possibility that the effects of insulin in the intact animal might be mediated through its action on one enzyme, creatine phosphokinase. I am not aware of any experimental evidence which repudiates this hypothesis, and I believe that further experimental enquiry is warranted.

I thank Mrs. Beverly Barnett for her technical assistance.

Optical Rotation of Irradiated Rhodopsin Solution

It has been suggested from spectroscopic observations of rhodopsin[1-3] that the photoisomerization of chromophore—11-*cis* to all-*trans* retinal—must be followed by a conformational change in the protein moiety of the rhodopsin molecule, which is considered to play an important part in the initiation of visual impulses. Such a conformational change in the protein should be determined by direct measurement of the optical rotation, as this is believed to be closely related to the conformation of the protein[4-6]. The purpose of the present investigation was to determine how far the rotatory polarization of rhodopsin solution changes in response to bleaching by light.

The materials were mainly digitonin extracts of cattle rhodopsin[7], and in some experiments 'Tween 80' extracts[8] and sonicated rod particles[9]. The optical rotation of rhodopsin solution was determined by an automatic recording spectropolarimeter (Yanagimoto Manufacturing Co., Ltd.) and a Rudolph polarimeter (type 200); vessels with light paths 0·5, 1, 10 and 20 cm long were used, around which was circulated aqueous ethylene glycol at constant temperature. Each sample was adjusted to a desired *p*H with 1/15 M phosphate buffer.

The optical rotation of rhodopsin solution was recorded in the range 620–220 mμ before and after irradiation with 10,000 lux for 1 min—this was found to bleach rhodopsin completely. Fig. 1 shows curves of the optical rotatory dispersion in rhodopsin digitonin solution before and after irradiation. In the range of wave-lengths longer than 350 mμ, the 'dark' curve is above the 'irradiated' one; between 330 mμ and 340 mμ they cross over. In the neighbourhood of 450 mμ, the two curves come into contact with each other (Fig. 1*a*). As shown in Fig. 1*b*, we always observed a minimum in the optical rotatory dispersion curves

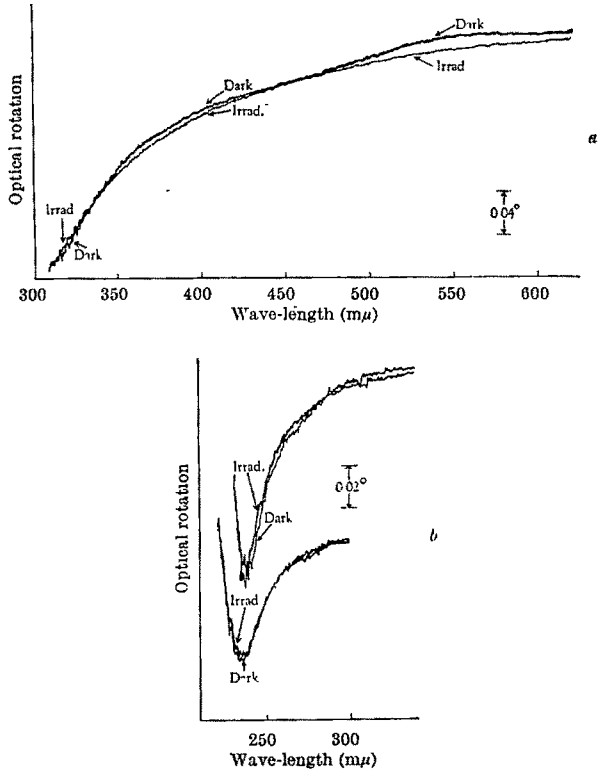

Fig 1. Curves for optical rotatory dispersion of rhodopsin digitonin solution before and after irradiation In Fig 1*a*, the optical density at 500 mμ is 1 98 (E_{500}/E_{400} · 0 32, *p*H 6 25, 15° C, irradiation · 10,000 lux, 1 min) In Fig 1*b*, the samples are diluted to 1/20 (upper two curves) and 1/40 (lower two curves)

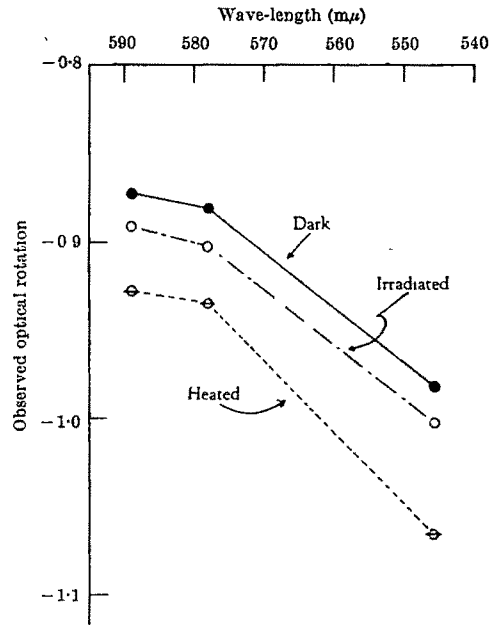

Fig. 2. Changes in observed optical rotation of rhodopsin solution after irradiation and after further heating at 80° C for 5 min (digitonin extract, *p*H 6·25; E_{500}, 0·45; light path, 10 cm; irradiation, 10,000 lux, 1 min, 28° C)

(Cotton effect). In the upper curves of Fig. 1*b*, the 'dark' curve is slightly lower than the irradiated one. It should be noticed that in this experiment the measurement in ranges shorter than 235 mμ was not accurate because of the deep absorbance of the sample, even though it was diluted to 1/20th for recording in the visible range. As for the lower curves in Fig. 1*b*, the sample was further diluted two-fold so that the measurement would be accurate down to 225 mμ. Thus a minimum of optical rotation is found at 235 mμ, although the difference in optical rotation between the dark sample and the one which is irradiated becomes less definite under these conditions.

The Cotton effect, which shows a minimum for optical rotatory dispersion at 235 mμ, is considered to result from the helical structure of the sample; after irradiation the optical rotation of the sample tends to increase in the ultra-violet range and to decrease in the visible range. These facts led us to suppose that the helical contents of rhodopsin might decrease in response to bleaching by light. Another noteworthy fact in the visible range is that the 'irradiated' curve seems to indicate a simple dispersion while the 'dark' curve indicates a rather complex one. In other words, the 'dark' curve appears to show another weak Cotton effect in the region of 450 mμ. Is this due to the chromophoric site giving rise to some optical activity ? This is unlikely, because the chromophoric site of rhodopsin is not considered to be optically active; (1) retinal itself is not optically active; (2) retinal is said to be bound with an amino group in rhodopsin[8], but it cannot interact with an optically active carbon to produce a new optical activity, because rhodopsin does not have a terminal α amino group[12], associated with an optically active carbon atom. Further experiments on this problem are in progress.

In order to compare the change of optical rotatory dispersion in rhodopsin with the results of conformational changes in other proteins, the optical rotation of the highly concentrated sample was measured between 610 mμ and 546 mμ. Fig. 2 shows the observed optical rotations of rhodopsin solution before and after irradiation at 28° C, and after heating at 80° C for a further 5 min. It can be seen from Fig. 2 that the optical rotation is decreased (increased in laevorotation) by irradiation and further

* Details in the text.
† Calculated from the results shown in Fig. 2.

decreased by successive heatings at any measured wave-length.

As the heating condition (80° C, 5 min) is sure to denature opsin[10], it is more likely that, after heating, an increase in laevorotation reflects a change to a more random conformation in the protein moiety of rhodopsin—such as is observed in other proteins and peptides. A similar tendency was found in 'Tween 80' extracts and in sonicated rod particles.

In general the specific rotatory power is used to compare the magnitude of changes in the protein conformation. As rhodopsin cannot as yet be purified, it is difficult to determine its optical rotation. If the change in the optical rotation of the sample after irradiation, however, is considered to be dependent on rhodopsin only, the difference of specific rotatory power before and after irradiation, $\Delta[\alpha]$, may be given from the difference of the observed rotations divided by the gram concentration of rhodopsin, which can be estimated from the molar extinction of 40,600 at 500 mμ and the molecular weight (40,000) (ref. 13). Thus we can compare the effects of light on rhodopsin in different experimental circumstances by means of $\Delta[\alpha]$, and further discuss the results in comparison with the values from other denatured proteins.

Table 1 shows the differences in the specific rotatory powers before and after irradiation. From these, we notice that there is a general tendency such that the shorter the wave-length the larger the value of $\Delta[\alpha]$; furthermore, at any wave-length, the values are similar irrespective of optical purity. The latter fact may support the concept that the $\Delta[\alpha]$ value depends on conformational change only in rhodopsin caused by the action of light. ($\Delta[\alpha] = \frac{\Delta\alpha \times 100}{lc}$, where $\Delta\alpha$ is the difference of observed optical rotations, l is the light path in dm, and c is the gram concentration of the sample.) In many helical polypeptides, we find a value of 100° for $\Delta[\alpha]_D$ (D denotes sodium D line near 589 mμ), the difference between $[\alpha]_D$ observed in helical conformation and that in a random coiled one. The value of $\Delta[\alpha]_D$ may be referred to as the contribution of the helical structure[4]. Heat-denatured rhodopsin shows the large value of 120°, while the bleached form exhibits about a third of the value of $\Delta[\alpha]_D$ (*p*H 6·25). The values at *p*H 5·2 are larger than those at *p*H 6·25. Opsin is known to be denatured more easily than rhodopsin[10], and *p*H 6·25 may offer a better condition to prevent further denaturation of opsin after bleaching than *p*H 5·2. So the larger values at *p*H 5·2 may be explained by the contribution of further denaturation of opsin after bleaching by light.

Although we consider that changes in the optical rotation of rhodopsin directly correspond to changes in its helical structure, some recent findings suggest that the changes in the optical rotation are caused by changes in the hydrophobic interaction related to protein conformation[11], and also by changes in the antiparallel cross β-structure[6]. We cannot as yet conclude that the observed change in the optical rotation is entirely concerned with the helical structure in rhodopsin, but it must somehow be related to the change in conformation of opsin.

We thank Prof. I. Honjo for his encouragement, and Dr. K. Hamaguchi and Dr. A. Kurono of the Institute for Protein Research for their criticism and help. This work was supported in part by a grant to Prof. I. Honjo from the Japanese Education Ministry and in part by a grant to one of us (Y. K.) from the Matsunaga Science Fund.

Infra-red Spectroscopic Investigations of a New Acid Mucopolysaccharide isolated from Human Gastric Juice

IN our earlier investigations[1,2] we have tried to isolate and characterize the acid mucopolysaccharides from the gastric wall in the dog and from human gastric juice.

In the gastric wall, in addition to hyaluronic acid and chondroitin sulphuric acid *B*, traces of a different type of sulphated mucopolysaccharide were found. We thought it possible that this constituent was secreted mainly with the gastric mucus, and so we collected large amounts of human gastric juice. The acid mucopolysaccharides were precipitated from this gastric juice with cetylpyridinium chloride (CPC) after hydrolysis with papain. The material precipitated with CPC would distribute into four fractions which were soluble in 0·3 N sodium chloride, and in 0·5, 0·6 and 0·8 N magnesium chloride, respectively. The chemical analyses of the fractions revealed that they contained fucose, galactose, glucosamine, galactosamine, sialic acid and sulphate, but no hexuronic acids. The molar ratios of the monosaccharide components were nearly the same in all fractions, but the degree of sulphation increased in the above-mentioned fractions from 0·3 N sodium chloride to 0·8 N magnesium chloride in this order.

The infra-red spectra of these fractions were obtained on a Perkin–Elmer model 237 spectrophotometer using a potassium bromide technique. 1 mg of the mucopolysaccharide (as the sodium salt) was mixed with 150 mg potassium bromide. Examples of the spectra of the 0·3 and 0·6 fractions are shown in Fig. 1. The spectra of fractions 0·5 and 0·8 are similar except that the area of the absorption band of sulphate (1,230–1,260 cm^{-1}) in fraction 0·5 is smaller and in fraction 0·8 somewhat greater than in the 0·6 fraction.

These spectra very much resemble the earlier[3,4] published spectra of acid mucopolysaccharides, namely, those of hyaluronic acid and chondroitin sulphates. These polysaccharides have an absorption band at 1,420 cm^{-1} which is due to the ionized carboxyl group[3]. This absorp-

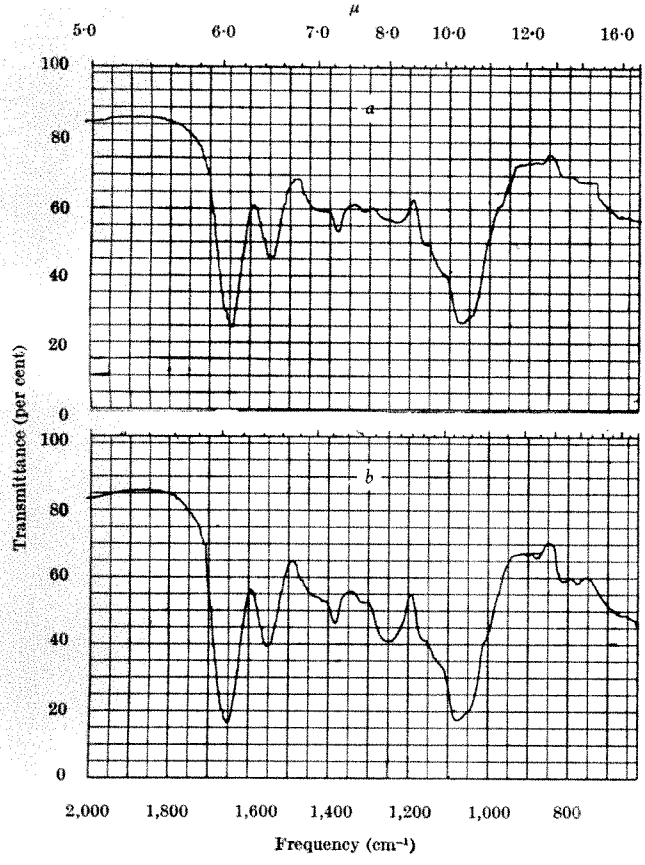

Fig. 1. Infra-red spectra of the fractions 0·3 (*a*) and 0·6 (*b*) of the mucopolysaccharide isolated from gastric juice

tion is quite weak in gastric juice polysaccharide (and may be due to sialic acid). The sharp band at 1,380 cm^{-1} may be due to the methyl group.

The absorption bands at 820 cm^{-1} and 775 cm^{-1} indicate that the polysaccharide from gastric juice resembles chondroitin sulphate *C* in this point. It may be that the sulphate groups occupy the C_6 position in the hexosamine moiety.

We conclude that these fractions represent various sulphation grades of the same polysaccharide. The non-sulphated form of this polysaccharide is not acidic by nature and is therefore not precipitable with CPC under the same conditions as are the actual acid mucopolysaccharides.

Formation of a Phosphonolipid by Larvae of the Housefly, *Musca domestica*

THE presence of 2-aminoethylphosphonate has been reported in ciliates[1] and in two sea anemones *Anthopleura elegantissima*[2] and *Metridium dianthus*[3]. The finding of the phosphonate in hydrolysates of lipid extracts obtained from these sources and the identification of its glyceryl ester in alcoholic extracts of the sea anemone suggest the natural occurrence of a diacylglycerylphosphonolipid. Rouser *et al.*[4] isolated a phosphonolipid from the sea anemone and identified it as a sphingolipid on the basis of its hydrolysis products. Baer and Stanacev[5] have synthesized the phosphonic acid analogue of cephalin.

Larvae of the housefly, *Musca domestica*, are able to replace lipid-bound choline and ethanolamine with a number of other amino- and *N*-methylated amino-alcohols when these are added to the larval diet[6,7]. We have shown that 2-aminopropan-1-ol, 3-aminopropan-1-ol, 1-aminopropan-2-ol and 2-aminobutan-1-ol are all extensively incorporated into the phospholipid in place of ethanolamine. The implied lack of specificity of the enzyme systems responsible for phosphatidyl-choline and -ethanolamine synthesis led us to speculate that the reported occurrences of 2-aminoethylphosphonate in lipid extracts may be a consequence of this combined with the availability of the phosphonate to the organism. To test this, housefly larvae were allowed to grow under aseptic conditions on a casein medium as previously described[6]. 2-Aminoethylphosphonate (Calbiochem) was added to the medium (75 mg/7·5 g casein) in the absence or in the presence of choline. After 6 days, the lipids of the larvae were extracted using the procedure developed by Folch[8]. Equal portions of these lipid extracts were hydrolysed by heating in sealed tubes containing 6 N hydrochloric acid at 110° C for 24 h and examined for the presence of 2-aminoethylphosphonate. The phosphonate which is stable under these conditions can be separated from other ninhydrin-positive compounds likely to be present in a lipid hydrolysate and from α-glycerophosphate and *ortho*-phosphate by two-dimensional chromatography on thin layers of silica-gel *H* (Merck) using 77 : 23 (v/v) 96 per cent ethanol : 28 per cent ammonium hydroxide in the first direction and 50 : 15 : 5 : 30 (v/v) methanol : 28 per cent ammonium hydroxide : 10 per cent trichloroacetic acid : water in the second direction. Using this system, a zone giving a positive ninhydrin test and travelling to the same position on the plate as 2-aminoethylphosphonate was found in both hydrolysates. When the ninhydrin-positive zones were scraped from the plate and digested with perchloric acid, they were shown to contain phosphorus. These zones could not be detected in hydrolysed lipid extracts from larvae grown in the absence of 2-aminoethylphosphonate.

Equal portions of the lipid extracts were chromatographed on thin layers of silica-gel *H* using 65 : 35 : 5 (v/v) chloroform : methanol : 7 N ammonium hydroxide as solvent. The separated lipids were detected by exposure to iodine vapour and a new lipid zone was detected in the extracts of larvae fed on the phosphonate. This zone gave a positive test with ninhydrin and travelled slightly slower than phosphatidylethanolamine. Two-dimensional chromatography using the alkaline solvent in the first direction and 50 : 25 : 7 : 3 (v/v) chloroform : methanol : glacial acetic acid : water in the second (Fig. 1*a*) showed that the new lipid travelled slightly faster than phosphatidylethanolamine in the acid solvent. This new lipid zone when separated on silica-gel using the alkaline solvent was scraped from the plate and extracted from the absorbent in 1 per cent acetic acid in methanol. The extract was hydrolysed with 6 N hydrochloric acid for 24 h at 110° C. The separated phosphatidylethanolamine zone was similarly treated. Examination of the hydrolysis products for 2-aminoethylphosphonate using the chromatographic system described here showed that the phosphonate occurred only in the hydrolysates of the new lipid zone. The lipid extracts were freed from neutral lipids and then subjected to the mild alkaline hydrolysis procedure developed by Dawson[9]. This removes the fatty acid moieties from any diacylglycerylphosphatides yielding the water-soluble glycerylphosphoryl derivatives of the base. Sphingolipids, plasmalogens and glyceryl ethers are not hydrolysed (or are only partially so) and remain insoluble in water. The 6 N hydrochloric acid

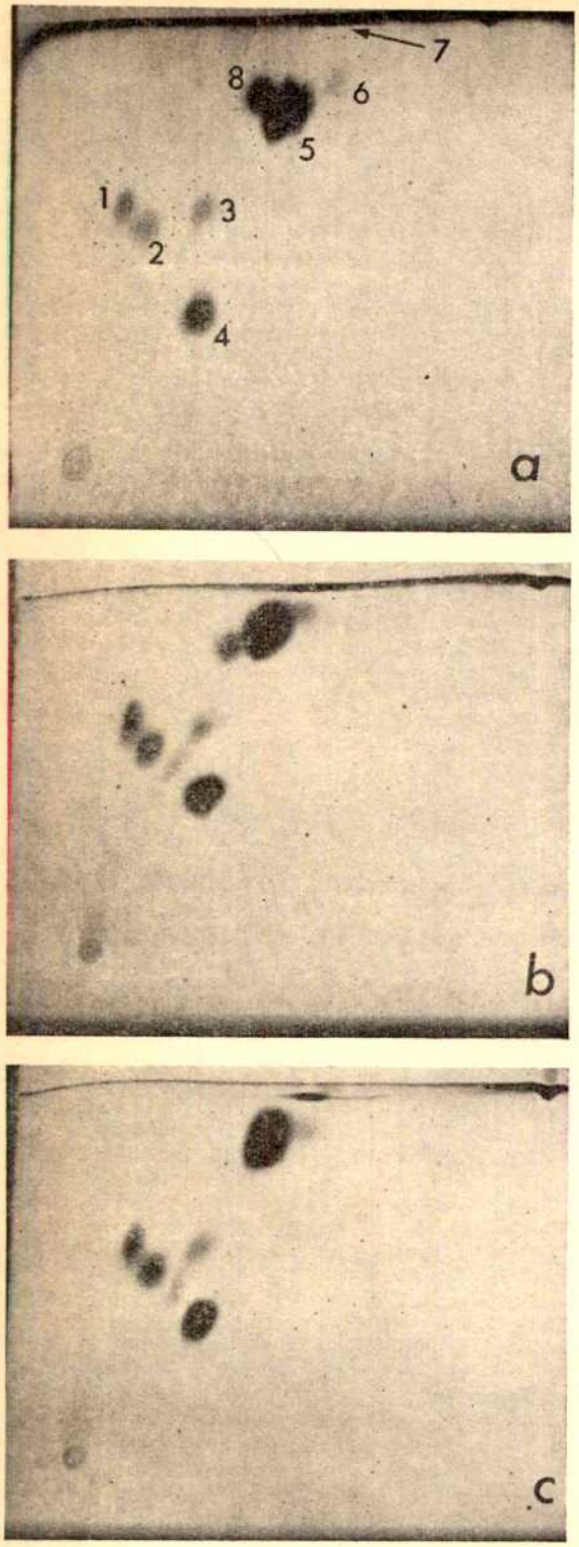

Fig. 1. Separation of phospholipids by two-dimensional chromatography on thin layers of silica-gel *H*. Horizontal direction: Chloroform followed by 65 : 35 : 5 (v/v) chloroform : methanol : 28 per cent ammonium hydroxide. Vertical direction: 50 : 25 : 7 : 3 (v/v) chloroform : methanol : glacial acetic acid : water. *a*, Lipid extract from larvae fed on medium containing choline and 2-aminoethylphosphonate. *b*, Lipid extract from larvae fed on medium containing choline and ethylamine hydrobromide. 10 μg of dimyristoyl-L-α-glyceryl-(2-aminoethyl) phosphonate added. *c*, As *b* but without addition of phosphonolipid. (1) Phosphatidylserine; (2) phosphatidylinositol; (3) lipid stable to dilute alkaline hydrolysis; (4) phosphatidylcholine; (5) phosphatidylethanolamine; (6) phosphatidylglycerol (?); (7) polyglycerophosphatide; (8) phosphonolipid

hydrolysates of the aqueous extracts after mild alkaline hydrolysis were shown to contain 2-aminoethylphosphonate whereas none could be detected in the hydrolysates of the lipids remaining after alkaline hydrolysis. A sample of dimyristoyl-L-α-glyceryl-(2-aminoethyl)-phosphonate (kindly supplied by Prof. E. Baer) had similar chromatographic properties to the new lipid (Fig. 1*b*). The lipid found in the larval extracts would seem to be a dialkylglyceryl-(2-aminoethyl)phosphonate and not a ceramide derivative, as such a compound would remain unhydrolysed by dilute alkali.

Table 1. PERCENTAGE DISTRIBUTION OF PHOSPHOLIPIDS CONTAINING ETHANOLAMINE AND CHOLINE AND OF THE PHOSPHONOLIPID IN EXTRACTS OF HOUSEFLY LARVAE FED ON DIETS CONTAINING ADDITIONS TO THE BASIC DIET AS INDICATED

Additions to diet	Percentage of total lipid phosphorus		
	Ethanolamine lipids	Choline lipid	Phosphono-lipid
None	80·5	1·7	0
2-Aminoethylphosphonate	70·9	2·7	5·1
Choline	65·4	17·0	0
Choline + 2-aminoethylphosphonate	54·6	18·1	8·4

Table 1 gives the percentage of the total lipid phosphorus determined in the phosphonolipid and phosphatidylcholine zones separated on thin layer. The values for lipid-bound ethanolamine were obtained after hydrolysis of the lipid extract and formation of the 2 : 4 dinitrophenyl-derivatives using the method of Axelrod *et al.*[10] (DNP-2-aminoethylphosphonate cannot be extracted with chloroform under the conditions used). The values obtained were expressed as a percentage of the total lipid phosphorus assuming a 1 : 1 molar ratio of ethanolamine to phosphorus. The smaller proportion of the phosphonolipid found in larvae reared in the absence of choline could be explained if the 2-aminoethylphosphonate were considered to be in competition with a larger amount of ethanolamine phosphate in such larvae compared with larvae in which choline is present in the diet. The larger percentage of phosphatidylethanolamine found in larvae reared in the absence of choline is consistent with this.

Inclusion of ethylamine hydrobromide in an equimolar concentration in place of 2-aminoethylphosphonate in the larval diet did not result in the formation of any phosphonolipid (Fig. 1*c*). Thus no enzyme, analogous to a phosphokinase but capable of producing a phosphonate, is present in housefly larvae. The present results together with our earlier observations show that a considerable lack of substrate specificity exists in the enzyme systems involving cytidine diphosphoryl bases for phospholipid synthesis. The experiments of Chojnacki[11] indicate that this is so for the rat, chicken and frog. The natural occurrence of phosphonolipids may well be a result of this and not of a requirement of any special metabolic function associated with this type of lipid.

Protein-disulphide Reductase Activity in Yeast

A STRAIN of *Saccharomyces cerevisiae* which in batch culture demonstrated little tendency to elongate was shown to do so in continuous culture when the supply of nitrogen was limited[1]. Because fewer cells elongated when sulphydryl compounds or sodium selenate were added to the medium, the sulphydryl–disulphide balance in the cells seemed to be implicated. Later investigations with the same yeast[2] revealed that the change in cell shape was not closely paralleled by changes in total and individual carbohydrates, proteins, nucleic acids and lipids of the cells. Attention was therefore directed to enzymes thought to be important in cell extension. Nickerson *et al.* placed special emphasis on a protein-disulphide reductase system controlling the formation of disulphide bridges in mannan-protein of the wall. They demonstrated in bakers' yeast[3] and *Candida albicans*[4] that after oxidation with potassium ferricyanide of isolated cell wall protein, the disulphide linkages were reduced by isolated mitochondria. The protein-disulphide-reductase activity was, however, very low in a mutant strain of *C. albicans* with elongated cells[4]. It was of interest, therefore, to compare activities of mitochondria isolated from elongated and ovoid cells of our strain of bakers' yeast.

In preliminary experiments, both the oxidized mannan-protein representing the cell wall substrate and the mitochondria were prepared by methods resembling those of Nickerson and Falcone[3,4]. Batch-grown ovoid cells were the source of the mannan-protein. Mitochondria were isolated from both ovoid and elongated cells of the same strain which had been continuously cultured at 25° C in glucose-limiting and nitrogen-limiting media respectively[2]. In all cases the dilution rate was 0·1 h^{-1}. Protein-disulphide-reductase activity of the mitochondria was measured after incubation for 1 h at 25° C with the substrate. The method of Boyer[5] was used for the assay of sulphydryl groupings. Mitochondria from ovoid cells showed much greater activity than an equal mass from elongated cells. The incubation mixtures of Nickerson and Falcone contained a "liver coenzyme concentrate", but a similar addition was shown to be unnecessary in the present experiments. Activity was not promoted by adding dihydronicotinamide adenine dinucleotide phosphate (NADPH), while less than 10 per cent increase in reduction was stimulated by 0·5 μmole of dihydronicotinamide adenine dinucleotide (NADH).

Electrophoretically pure ovalbumin (Sigma grade) furnished an alternative and convenient substrate in place of mannan-protein. Ovalbumin and mitochondria derived as before from ovoid and elongated cells were incubated for 30 min, but in further work the incubation period was reduced to 10 min (Table 1). The results were supplemented by using mitochondria of ovoid cells continuously cultured in phosphate-limited medium. There was no substantial increase in activity when NADH was added to the various incubation mixtures.

Table 1

Culture medium	Cell shape	Incubation period (min)	—SH production*
Nitrogen limiting	Elongated	30	183·1
Glucose limiting	Ovoid	30	649·3
Nitrogen limiting	Elongated	10	98·2 ± 15·2
Glucose limiting	Ovoid	10	248·1 ± 25·0
Phosphate limiting	Ovoid	10	208·1 ± 28·4

* Expressed as mμmoles cysteine/mg protein, means of four results after subtraction of control values. Protein-levels of mitochondria estimated routinely as total nitrogen × 6·25 but confirmed in selected cases by the Folin–Ciocalteau method (ref. 6). Mitochondria in phosphate buffer (*p*H 7·0) (0·5 ml.) and ovalbumin solution adjusted to $E^{280}_{1\,cm} = 1·0$ (0·25 ml.) and incubated in an evacuated desiccator at 25° C.

Table 2

Culture medium	Cell shape	—SH production* Ovalbumin	MP(*E*)	MP(*O*)
Nitrogen limiting	Elongated	101·7 ± 11·9	0·00	0·00
Glucose limiting	Ovoid	375·4 ± 25·5	111·4	123·2
Phosphate limiting	Ovoid	312·8 ± 17·5	—	—

* 0·1 ml. mitochondrial supernatant and 0·1 ml. ovalbumin solution or 0·5 ml. mannan-protein incubated for 1 min at 25° C in air with results expressed as mμmoles cysteine/mg protein, mean of three results after subtraction of control values. MP(*E*) and MP(*O*) represent mannan-protein of elongated ovoid cells, respectively.

The results suggested either a considerable difference in protein-disulphide-reductase activity of the mitochondria of ovoid and elongated cells or differences in permeability of the mitochondrial membranes. Accordingly the experiments with ovalbumin and mannan-protein were repeated using mitochondria preparations which had been disrupted sonically and the membranes removed by centrifugation at 20,000*g* for 20 min. The activities shown in Table 2 were not significantly increased when NADH was added. They demonstrated for the first time that the difference in activity between mitochondria of elongated and ovoid cells was not due to permeability effects, and provided evidence that there is little difference between the mannan-protein of elongated and ovoid cells as substrates.

Activity of the mitochondrial supernatant was lost when 40–60 per cent saturated ammonium sulphate was added to the preparation. The material precipitated by the addition was taken up in 5 mM phosphate or *tris* buffer at *p*H 7·0 and dialysed overnight against similar buffer. When presented with ovalbumin (0·25 mg) as substrate, the dialysed material (adjusted to the usual absorbance) displayed no disulphide-reductase activity after 1 min at 25° C. Addition of 0·25 μmole NADH to the incubation mixture, however, brought about the production of 1,360 mμmoles cysteine/mg protein. It is clear, therefore, that while protein-disulphide-reductase in yeast mitochondria is not dependent on the mitochondrial membrane, it is closely coupled with either NADH or an alternative coenzyme.

Trypsin Inhibition by Phenylmethylsulphonylfluoride with Reduced Wool as Substrate

WE are trying to dissolve native proteins from wool by the method of limited proteolysis[1,2]. Unreduced wool is not attacked by trypsin and so, in our experiments, wool has been reduced under the mildest possible conditions which will allow trypsin digestion. We believe that these conditions do not cause denaturation of the wool[3]. Apparently, large protein fragments are dissolved from the reduced wool by trypsin, and in a synthetic boundary run[4] in the Spinco model *E* ultracentrifuge, the unfractionated solution gave a schlieren peak, sedimentation coefficient of 3·1. One obstacle to further characterization of the dissolved proteins is the enzyme in the solution, which may continue to digest the fragments it has released from the fibre. This communication describes experiments which show that the inhibitor phenylmethylsulphonylfluoride (PMSF)[5] will arrest the reaction of trypsin with reduced wool.

Accurately weighed samples of wool were reduced under controlled conditions, rinsed and treated with trypsin solutions. Fig. 1 shows the results of a series of experiments in which different amounts of inhibitor were added to trypsin solutions at different times before introducing the reduced wool sample. A comparison was made between the amount of protein dissolved by the inhibited

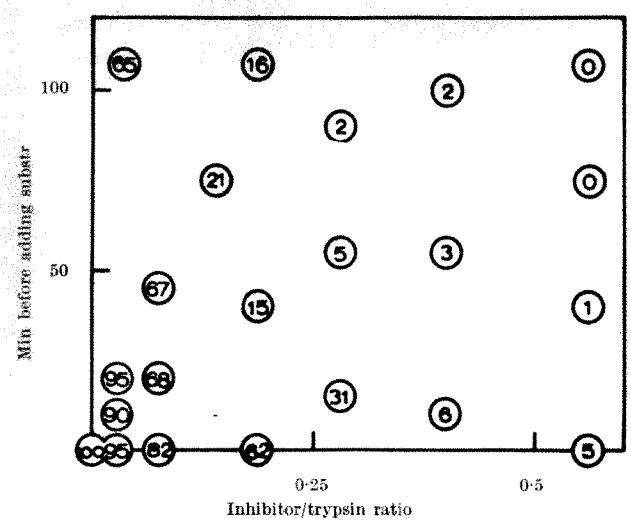

Fig. 1. The numbers in the circles indicate the amount of protein dissolved from reduced wool by trypsin solutions inhibited by PMSF, as a percentage of the amount dissolved by the uninhibited trypsin solution. Lincoln wool was purified by extraction with methylene chloride, dried at room temperature, and conditioned at 65 per cent relative humidity and 22° C so that it absorbed 15 per cent of water. Samples of about 0·2 g were accurately weighed out and reduced for 18 h at 4° C in 0·2 M thioglycollic acid, 0·1 M disodium hydrogen phosphate adjusted with sodium hydroxide to *p*H 9·75. In this treatment 19 per cent of the wool dissolved. The reduced wool was rinsed in 0·1 M disodium hydrogen phosphate at *p*H 8·0, and then placed in 4 ml. of a trypsin solution (wool : enzyme ratio, 50 : 1) in the same buffer, to which different amounts of PMSF dissolved in 45 per cent *i*-propanol–water had been added at various times before the wool was added. Digestion was allowed to occur for 50 min at 20° C after which the wool was removed and the solution centrifuged at 100,000*g* for 15 min. The concentration of protein in solution was measured in a Zeiss interferometer. If inhibitor is not added to the trypsin solution, 64 per cent of the reduced wool is digested

trypsin solutions and the uninhibited solution. Trypsin activity is almost completely inhibited if, for example, an amount of PMSF equal to 0·28 times the weight of enzyme is allowed to react with the enzyme for 55 min at *p*H 8·0 and 20° C.

IMMUNOLOGY

Antibody Production in Bursectomized Chickens given Repeated Injections of Antigen

CHICKENS which have had their bursa of Fabricius removed at birth are unable to produce adequate quantities of antibody[1]. Assay of spleen sections from such bursectomized birds has revealed an almost complete failure of the pyroninophilic cells to proliferate after an intravenous injection of antigen[2]. In chickens, many basophilic lymphoid cells are situated outside the spleen and the bursa, and cells of the plasmacytic series are found scattered throughout the wall of the intestine, or accumulated in the tonsilla caecalis[3]. For this reason, it cannot be assumed that the deficiency in antibody formation of bursectomized chickens is absolute. Indeed, the present experiment demonstrates that the compromised antibody function of surgically bursectomized birds can be repaired by multiple injections of antigen.

Rhode Island Red chickens were used. Surgical bursectomy was performed on one-day-old chickens. All operated birds were checked at autopsy for bursal remnants, and only those in which no residual bursal tissues were to be found were taken into consideration. One group of bursectomized and unoperated birds was immunized when 8 weeks old, and another group was immunized when 6 months old. 2·0 ml. of a 10 per cent suspension of washed human O red blood cells were injected into the wing veins of the chickens; a further three injections were given with an interval of 24–26 days between injections. Blood samples were taken 9 days after antigen injection and sera examined for the presence of any haemagglutinins. All sera were assayed for mercaptoethanol-sensitive antibody according to the method previously described[4]. Thymus, spleen, bursa, tonsilla caecalis and fragments of intestine were taken for histological examination.

Table 1. HAEMAGGLUTININ PRODUCTION (LOG$_2$ MEAN TITRE) IN NEONATALLY BURSECTOMIZED CHICKENS HYPERIMMUNIZED WITH HUMAN ERYTHROCYTES

Group	Age at time of primary challenge	Primary response	Secondary response	Tertiary response	Quaternary response
Unoperated	8 weeks	7·7 (14/14)*	8·0 (14/14)	8·6 (12/12)	9·2 (12/12)
Bursectomized	8 weeks	0 (0/13)	4·5 (10/13)	5·7 (10/13)	6·6 (10/12)
Unoperated	6 months	8·8 (8/8)	10·0 (8/8)	—	—
Bursectomized	6 months	0 (0/10)	6·1 (10/10)	—	—

* In parenthesis, *nominator*, No. of chickens with haemagglutinins; *denominator*, No. of chickens in group.

Table 1 summarizes the results of antibody production in hyperimmunized unoperated and bursectomized chickens. The titre of haemagglutinin increases as the hyperimmunization progresses in control groups. Birds of both bursectomized groups failed to produce any detectable quantities of circulating antibodies after primary immunization. However, they did respond to some extent to the second injection of antigen, and the third and fourth injections caused a further increase in antibody production.

Histological examination of the spleen sections of unoperated chickens has revealed large areas of mature and immature plasmacellular elements[2]. In the spleen of hyperimmunized bursectomized chickens the size of the area occupied by the proliferating pyroninophilic cells varied from individual to individual. The spindle-shaped thickenings of arterial subterminal branches were surrounded by a large number of pyronin-positive cells. An increase in the number of plasmacellular elements was also noted in the tonsilla caecalis and intestine of unoperated and bursectomized chickens after multiple injections of antigen. Plasma cells were found in the thymus of chickens from all experimental groups; in six cases round-shaped aggregates of cells, which closely resembled the germinal centres seen in the spleen and caecal tonsil, were observed in the medullary portion of the thymus (Fig. 1). No apparent alterations were noted in the bursa of hyperimmunized control chickens. These morphological changes in the spleen, tonsilla caecalis and gut, and probably in the thymus, following multiple immunological stimulations could well account for the increase in level of circulating antibodies during hyperimmunization.

After primary immunization, haemagglutinins in the circulation of normal chickens were predominantly mercaptoethanol-resistant, and antibodies produced in the course of hyperimmunization continued to be of this type. On the other hand, a preponderant production of mercaptoethanol-sensitive antibodies by bursectomized chickens was noted. Using a soluble antigen, Benedict *et al.*[5] showed that the sera obtained after secondary antigen injection have some antibodies which were

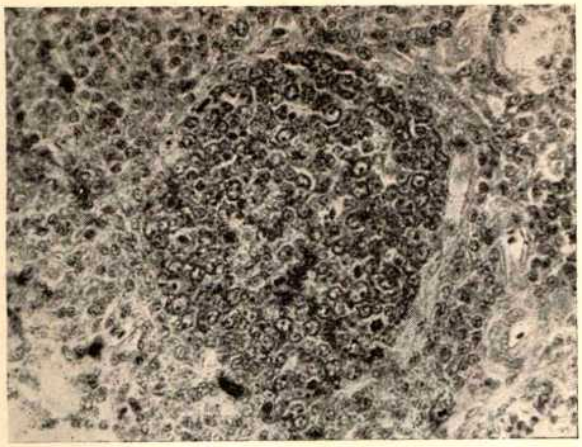

Fig. 1. Germinal centre in the thymus of a bursectomized hyperimmunized chicken. (Stained with methyl green–pyronin)

resistant to mercaptoethanol and sedimented as 7*S* immunoglobulin.

It has been shown by others[6] that lymphoid tissue of the gut is capable of producing antibodies, and that the intestinal bacterial flora probably continuously stimulates the lymphoid tissue in the gut. The absence of lymphoid masses in the intestinal wall of germ-free animals gives an indication of the important part played by the intestinal flora and its products in the multiplication and differentiation of intestinal lymphoid cells[7]. The question still remains, however, as to why these cells (which are present in large numbers in the intestine of bursectomized chickens) do not manufacture circulating antibodies following the first intravenous injection of antigen. So far as histological changes in the spleen and gut are concerned, it would also be intriguing to know why the proliferation of pyronin-positive cells of bursa-less chickens occurs solely after the secondary and subsequent antigenic stimulations. It can further be assumed, however, that in bursectomized chickens there is an inhibitor of antibody synthesis which is particularly related to the primary response, or that bursa-less birds are deficient in some factors (hormone ?) necessary for the initiation of antibody formation. Consequently, the priming capacity of antigen in unoperated chickens is superior to that in bursectomized ones. In any event, the phenomenon described requires careful scrutiny in any discussion of the transient vulnerability of antibody-synthesizing mechanism due to extirpation of the bursa which can be repaired by hyperimmunization, regardless of whether or not there are more than two primary organs (thymus and bursa) in birds which control the immunological machinery of the body.

Immunochemical Reactions of Conalbumin and its Metal Complexes

IMMUNOCHEMICAL methods have been extensively used in protein chemistry for the elucidation of structural changes in proteins. More recently, this method has been successfully used to demonstrate possible conformational and configurational changes in the protein molecule as a result of its interaction with small molecules and prosthetic groups[1,2]. Immunochemical differences, for example, have been reported for horse oxyhaemoglobin and deoxyhaemoglobin, as well as for metmyoglobin and apomyoglobin[1,2].

These investigations have prompted our interest in the application of immunochemical methods for the investigation of the antigenic properties of metallo-proteins as compared with the apo-proteins. We found earlier that even small structural changes cause measurable changes in the rate of the antigen–antibody reaction[3]. The rate of antigen–antibody reaction can be conveniently followed by measuring the change in the light scattering of the antigen–antibody reaction mixture. The method of measuring light scattering also has the advantage that it is a direct measure of the antigen–antibody interaction, which requires no alteration of antigen or antibody by labelling, or by the addition of precipitating agents as other techniques do.

The protein chosen for this investigation was conalbumin (CA)—a well-known metal-binding protein from egg albumen[4]. CA forms a red-coloured stable complex with two atoms of Fe^{3+} per molecule of protein. It also forms weaker complexes with Cu^{2+} and Zn^{2+}. The metals are readily dissociated from the protein at *p*H values below 6. Tyrosine phenolic and histidine imidazole groups have been implicated at the metal-binding sites of this protein[5–7]. Three-times crystallized CA was prepared essentially as in earlier investigations, use being made of the carboxymethylcellulose cation exchanger[8].

Bovine and anti-conalbumin (ACA) was prepared as described earlier[3] and contained 3·7 mg antibody protein/ml. antiserum. All measurements of light scatter were performed with reagents which had been passed through 'Millipore' filters. Various concentrations of the antigens were mixed with a constant amount of 25 × diluted ACA in 0·1 M borate buffer (*p*H 8·2) directly in a 1 × 1 cm rectangular quartz cuvette. The light scatter of the antigen–antibody reaction mixture was measured in an Aminco–Bowman spectrophotofluorometer at 90° angles. The incident beam was at 334 mμ and the scattered beam at 668 mμ. The light intensity of the scattered light was directly recorded on a Honeywell Electronic 19 recorder with a chart speed of 1 in./min. The results are expressed as the increment in light scatter (read on the transmittance scale ΔT) in the first 2 min of the reaction. The light scatter increased almost linearly with the antigen concentration in the 'antibody excess' zone; therefore, comparisons of the immunoreactivity of the systems examined were made in the 'slight antibody' excess zone. Fig. 1 illustrates typical results from such experiments.

Because the most significant decrease in the rate of the antigen–antibody reaction was caused by FeCA, we investigated the possible effect of Fe^{3+} itself on antibody–antigen reaction. The results are given in Table 1.

These experiments were conducted under the same conditions as those in Fig. 1. The free Fe^{3+} added was equal to the stoichiometric amount needed for the FeCA complex formation (2 moles Fe^{3+}/mole CA). It is evident from Table 1 that the addition of Fe^{3+} to the ACA before, after, or simultaneously with the addition of CA or FeCA does not influence the rate of the reaction. This indicates that the free Fe^{3+} in the applied concentration, does not interfere with the antibody or with the immuno-reaction itself. These results also indicate that the antigen–antibody reaction occurs much faster than the Fe^{3+}

Table 1. EFFECT OF Fe^{3+} ON THE CA–ACA REACTION

No.	Reaction mixture*	ΔT†
1	ACA + CA	13·0
2	ACA + FeCA	5·0
3	ACA + CA + Fe^{3+}	14·0
4	ACA + FeCA + Fe^{3+}	4·5
5	ACA + Fe^{3+} + CA	12·0
6	ACA + Fe^{3+} + FeCA	6·5
7	ACA + { Fe^{3+}, CA simultaneous	13·0
8	ACA + { Fe^{3+}, FeCA simultaneous	5·0

Protocol: 1·0 ml. antibody + 0·1 ml. antigen + 0·1 ml. Fe^{3+} $\frac{\text{mixed}}{\text{in 6–10 sec}}$ light scatter recorded.

* The composition of the reaction mixtures was the same as for Fig. 1. The extra Fe^{3+} added was $3{\cdot}74 \times 10^{-4}$ μmole per ml. of reaction mixture.

† ΔT, increment in the light scatter between 0 and 2 min of the reaction.

binding by CA—at least under the conditions used in this experiment.

The increase in the light scatter during an immunochemical reaction is an indication of the combining properties of the antigen with its antibody and thus represents molecular events which are occurring during this interaction[9,10]. It is, therefore, expected that alteration in the structure of antigen may affect these interactions. The decreased antigenic reactivity of metal–CA complexes as compared with CA may, therefore, reflect the alteration in the protein structure as a result of chelation of metal ions by the protein. The interaction of metal with CA may result in configurational changes of the protein molecule, as well as in masking of important functional sites (antigenic sites) which may be required for a maximum antigenic reaction.
